In a curious novel, that lacks the wit and vigorous originality of his previous book, Jacobson offers a pastiche of the fashionable preoccupation with the novelist's involvement in his characters.

The action of the story moves between the history of Timothy Fogel's conception, birth and subsequent life and a room in which the narrator sits, "trapped in the lives" he is writing about. Gradually it appears that he and the paranoic schizoid Timothy are aspects of the same personality and what had previously seemed to be the writer's room in a Swiss hotel now appears as Timothy's room in a psychiatric hospital.

R. Prawer Jhabvala (b. 1927).

Born in Germany to Polish parents, Mrs. Prawer Jhabvala accompanied them to England in 1939. In 1951 she married an Indian architect and now lives in Delhi, and it is Delhi which provides the setting for most of her novels and short stories.

These gentle comedies of manners have been warmly praised by critics. They are conventional in form and make no great demands upon the reader, but offer agreeable, light-hearted entertainment. Generally available examples include *To Whom She Will*, 1955; *The Nature of Passion*, 1956; *Esmond in India*, 1958; *The Householder*, 1960; *Get Ready For Battle*, 1962; *A Backward Place*, 1965; *A New Dominion*, 1973.

B. S. Johnson (1933–73).

Johnson has published six novels: *Travelling People*, 1963 (Pa); *Albert Angelo*, 1964 (Pa); *Travel* 1966; *The Unfortunates*, 1969; *House Mother Normal*, 1971; *Christie Malry's Own Double Entry*, 1973.

With the publication of his third novel, *Trawl*, Johnson gained a reputation as one of the most skilful of the English *avant garde*, but his later work has been disappointing. The dominant influences upon his novels have been those of the eighteenth-century Sterne and Beckett (*q.v.*). Johnson prefaces his second book, *Albert Angelo*, with a quotation from Beckett's *The Unnamable*: "When I think . . . of the time I've wasted on these bran dips . . . when I had me on the premises." Towards the end of his novel, Johnson writes, "im trying to say something about me through him albert . . . when whats the point . . . telling stories is telling lies . . . I want to tell the truth about my experience." Unlike Beckett, Johnson seems to feel it is possible to "tell the truth."

His expressed aims have much in common with Nathalie Sarraute's, "Today everybody is well aware, without being told, that la Bovary c'est moi . . . the important thing now . . . is to reproduce as clearly as possible the wealth and complexity of the world of the psyche." However in *Albert Angelo*, *Trawl* and *The Unfortunates* Johnson seemed to move farther than Sarraute towards abandoning the pretence of writing anything more than the most thinly disguised autobiography. These three novels bear superficial, stylistic resemblances to Beckett's *Molloy* trilogy: incidents, scenes and characters from one novel re-appear or are referred to in another and the three protagonists now named, now unnamed are the same person. But, whereas in Beckett's work, personal experience has undergone imaginative transmutation, Johnson particularly in the High Wycombe scenes of *Trawl* and in most of *The Unfortunates*, conveys the feeling of personal experience vividly remembered rather than recreated, and in his concern to "reproduce the moment to moment fragmentariness of life and to echo it in technique" Johnson is often undiscriminating, clever but unimaginative. Sterne's use of the blank page in *Tristram Shandy* was witty and original. Johnson's use of eight in *House Mother Normal* is rather a tiresome waste of paper than a valid expression of blank minds. Yet he is a writer of great natural gifts. His earlier novels are often highly entertaining, while *Trawl* as a whole gives truly imaginative expression to a young man's struggle to come to terms with life.

Doris Lessing (b. 1919).

Doris Lessing has published poems, short stories, plays and other books, including *Particularly Cats*, and *In Search of the English*, but, she is probably best known for her novels.

She was born in Persia, but her British parents soon moved to Rhodesia, where her mother, who had enjoyed social life in Persia, "found herself sitting in the middle of the bush in a thatched hut, with her visiting cards and her piano and her curtains from Liberty's"—a prototype of her daughter's Mrs. Quest in *The Children of Violence*.

At the age of eighteen, Doris Lessing went to Salisbury to work as a telephone operator. There she says, she had "the kind of compulsive good time described in *Martha Quest*."

In 1949 she came to England carrying the manuscript of her first novel, *The Grass is Singing*, which was quickly published and outstandingly successful. Her subsequent work has revealed a writer who combines an almost Victorian quality of "high seriousness" with an extremely flexible, creative approach to the form of the novel.

In varying ways, and usually with a remarkable degree of objective sympathy, her fiction is concerned to explore how people are affected by belonging to minority groups, and how society reacts to such minorities. At first she was particularly concerned with the position of white Africans, of those with left-wing sympathies in conservative societies and with women who resent that ours is still mainly a man's world—a theme of Mrs. Lessing's work long before the days of Women's Lib! In *The Four-Gated City* and most particularly in *Briefing for a Descent into Hell*, she explores the situation of those deemed insane.

The Grass is Singing. 1950. P.

In this accomplished first novel, set in South Africa, Doris Lessing writes of the tortured lives of Dick and Mary Turner, isolated members of the White agricultural community, and of their relationships with their African servants.

The Children of Violence—*Martha Quest*, 1952, *A Proper Marriage*, 1954, *A Ripple from the Storm*, 1958, *Landlocked*, 1965, *The Four-Gated City*, 1969 (all Pa).

Reading the first two books of this sequence one is constantly reminded of George Eliot. Not only do both novelists employ similar techniques, but they share an intense concern with problems of morality and ethics. Martha Quest, the novel's passionately idealistic heroine, recalls Dorothea Brooke and Maggie Tulliver, and is presented here with the same kind of objective, ironic sympathy that characterises George Eliot's treatment of Dorothea.

In the third and fourth books, however, the portrayal of Martha is almost overwhelmed in a detailed study of the social and political life of Rhodesia during the Second World War. Fascinating as social documents, from a literary viewpoint these volumes at first seemed less satisfying than the earlier ones, but their function within the whole novel became clear upon the publication of *The Four-Gated City*.

In this volume, which is set in England, the political and social questions of the last twenty years play a prominent part, but Mrs. Lessing now emphasises their effect upon the individual as she depicts the mature Martha's gradual realisation of the ways in which a person's life and personality can be distorted by unquestioning acceptance of an ideology, and how this can lead him to damage others, as well as himself, by denying the importance of individuals and dismissing their intuitive and imaginative insights.

This final volume has an appendix whose action is set in the future, after a series of catastrophies has devastated much of the world. This section reads convincingly, but follows rather awkwardly upon the naturalism of the rest of the novel.

The Golden Notebook. 1962. P.

The content of this novel is most interesting but its form is awkward. The first part of each of its sections recounts incidents in the lives of the heroine, Anna, and her friends and acquaintances. The rest of the novel consists of extracts from notebooks, some diaries, some stories, in which Anna, a novelist, writes of her feelings about her work and her experiences as a disillusioned member of the Communist Party and as a divorcee who hopes to remarry.

Briefing for a Descent into Hell. 1971.

A middle-aged man is admitted to a psychiatric hospital. He has been found wandering on the Embankment and is thought to be suffering from delusions and loss of memory. He says he is on a raft in mid-ocean and when asked his name calls himself now Jason, now Jonah, now Sinbad. Two doctors treat him. One, named X, has a closed mind; the other, Y, tries to understand, but is blinkered by the preconceptions of his training. Neither therefore realises that their patient's claim to be a sailor is a symbolic expression of the fact that, like the Ancient Mariner, he is making an intense, spiritual voyage.

The doctors seek to "cure" him, at first by heavy sedation, against which he struggles purposively to continue his voyage. After purgatorial experiences on an island to which he has been carried by a porpoise (his purposiveness) he is taken up into the heavens and realises the perils facing mankind on our overcrowded, polluted planet, where men fight for egocentric ends. The voyager is then implicitly present at a "briefing" of celestial beings who are about to "descend" and suffer incarnation upon earth in the hope of saving mankind. The protagonist is reborn with them, but "shades of the prison house" quickly rob him of his heavenly vision.

His "voyage" now ended and the drugs withdrawn as "unsuccessful" the patient is apparently normal, except that he still has not regained his memory and he is unusually sensitive to others' feelings. There follows a series of letters giving clear impressions of his usual personality as an insensitive and rather unpleasant Classics don named Watson. Later, at the request of Dr. Y, Watson writes a vivid account of war-time experiences of love and self-sacrifice among the Yugoslav partisans giving moving expression to his new awareness of man's creative potentialities. Now he befriends another patient; then, urged by the doctors, he eventually agrees to undergo E.C.T., not that he shares their hopes that it will restore him to "normality", but because it seems to offer his only hope of regaining the memory of his celestial vision. After the "therapy" he emerges as his usual, crass self.

The whole account is interposed with extracts, at once comic and frightening, from the patient's hospital case notes and his conversations with the uncomprehending nurses and doctors.

In an interview published in *The Guardian* of 14 April 1971, Mrs. Lessing said she believes a mental breakdown may result from "the more important part of a person" trying to break through the carapace of social conditioning. This idea is familiar not only from the popular work of R. D. Laing, but from such earlier studies as Karen Horney's *The Neurotic Personality of Our Time* (1937). Some readers may dispute the validity of the idea. However, like all true artists, Doris Lessing gives powerful and original expression to her themes and although in the "heavenly" section her book falters briefly towards didacticism, it otherwise induces that "willing suspension of disbelief" which is the acid test of good writing.

In this novel, as in *Golden Notebook*, she employs a great variety of narrative forms, but the realism of her previous work is here replaced by vivid poetic symbols and Swiftean satire. The result is a most moving, compassionate book.

The Summer Before the Dark. 1973.

As in *The Four-Gated City* and *Briefing for a Descent into Hell* Doris Lessing here writes of a period of self-discovery, but her new book, firmly placed in its contemporary setting, eschews the apocalyptic overtones of the two previous novels. It seems at once simpler and more complex than either.

An underlying theme is the process of adjustment to growing old. Some of the heroine's feelings have affinities with those expressed by members of the Women's Liberation Movement, but Doris Lessing is interested in a much more general question than the problem of typed sexual roles and, as always, she is concerned with an exploration and expressing of feeling, rather than with the confirmation or refutation of a theory.

Her heroine, Kate, is a middle-aged housewife suddenly faced with the realisation that she is no longer necessary to her grown-up family. Her struggle towards greater maturity through accepting that the time has come for her to relinquish motherhood is paralleled by the struggles of two younger people. One, a man of thirty-two is confronted by the realisation that he has grown too old to continue with the irresponsible life of a carefree youngster. The second, a girl in her early twenties, is desperately seeking to define what womanhood for her involves. There is also implied a contrast between the heroine's struggle to accept the fact that she is growing old and her older husband's attempts artificially to prolong his youth by dressing in the height of fashion and pursuing casual affairs with younger women. Meanwhile, unobtrusive references to the world's growing shortage of fuel and to the harshness of life in underdeveloped countries, place the novel's themes in a wider context.

The story incorporates passages of mythical power and beauty. It is presented chiefly from Kate's viewpoint but is written in the third person in a tone of paradoxically calm intensity. With poetic skill it traces the heroine's at first tentative, but gradually more resolute, quest for understanding and acceptance of the function and purpose of her life and, by implication, of all our lives.

Mrs. Lessing has here created a remarkably vivid and authentic expression of the experience of intense emotional and spiritual adjustment. At the same time her novel constitutes a penetrating criticism of our society and the immaturity and confusion of its values.

Malcolm Lowry (1909–57).

While many novelists' work is to some degree autobiographical, Lowry's writing seems to have been inspired by a sense that the events of his own life formed significant patterns. Some knowledge of these events facilitates understanding of the versions of his unfinished novels which have recently been published by his wife. The best available guides to his life and work are *The Selected Letters of Malcolm Lowry*, edited by H. Breit and M. B. Lowry, and D. Day's *Malcolm Lowry*, 1974.

Born in Birkenhead, Lowry, who once described himself as "a conservative Christian Anarchist at heart", early rejected the ideals of his prosperous father and, inspired by reading Conrad, he ran away to sea, working as bosun's boy on a tramp steamer to the Far East. Later, while at Cambridge, he spent a long vacation as fireman on a Norwegian ship. These experiences inspired a talented undergraduate novel. *Ultramarine*, 1933, and for the rest of his life Lowry remained fascinated by the sea. He became a great admirer of the work of Herman Melville.

Lowry's career, dogged by misfortune and suffering, culminated in an early death as the result of a tragic accident. But in the most difficult period of his life cheerfulness kept "breaking through" and he found great happiness in the years he and his second wife, Margerie, spent in a beach shack at Dollarton, in British Columbia. Here, the simplicity and friendliness of life in a beautiful setting, among kindly, independent fishermen and boatbuilders, combined with the joy of his second marriage, enabled Lowry to control that compulsive drinking which had earlier threatened his ruin.

Lowry's reputation derives from the one complete work of his maturity, the magnificent *Under the Volcano*. He left a mass of unfinished writing. The published versions of this work are uneven in quality, at times approaching the concentrated poetic style of *Under the Volcano*, at others lush and mawkish.

Lowry conceived his novels as parts of a modern *Divine Comedy*, to be called *The Voyage That Never Ends*. This was originally planned as a trilogy, with *Under the Volcano* as the first volume. A *nouvelle*, later called *Lunar Caustic*, was to be expanded to become the second, "purgatorial" book. The "paradisal" third volume was a novel called *In Ballast to the White Sea*.

However, in 1944, a fire destroyed the Lowrys' home and he lost everything except a draft of *Lunar Caustic* and the manuscript of *Under the Volcano*. This novel then became the centrepiece of the replanned epic, which Lowry now conceived in six volumes. They included a Mexican trilogy, *Dark as the Grave Wherein My Friend is Laid*, *Eridanus* and *La Mordida*. Drafts of the first and third of these books were completed but material intended for the second volume, *Eridanus*, became incorporated in short stories *The Forest Path to the Spring* and *Gin and Goldenrod*. Some of the rest grew into another novel, *October Ferry to Gabriola*. All were left unfinished, but Lowry's individual method of composition makes it possible to gain some idea of what the completed work would have been like.

It is known that Lowry's novels had their genesis in his journal-notebooks. He wrote many

drafts of a work before composing a final version and left several complete drafts of each of his unfinished books. His widow, aided by American scholars, has spliced together the various drafts of each book to produce a composite version. Unfortunately, Lowry's notebooks and his original completed drafts have not been published and one novel, *La Mordida*, has yet to appear in any form.

Under the Volcano. 1947. P

"Man cannot live without love" is the main theme of a splendid novel set in Mexico and giving poetic expression to the age-old dilemmas of man's relationship to God and to his fellow human-beings.

In a portrait of the tortured world of addiction, remarkable in its objectivity, Lowry presents the alcoholic Firmin, a former British consul, as a tragic hero in the tradition of Marlowe's Faustus.

The novel has an exciting story and Lowry expresses his themes not only through subtle allusive images but also through the events of the narrative, the lives and feelings of the characters and vivid descriptions of Mexico and its people.

The action takes place in 1938 on the Day of the Dead—all Souls' Day—the occasion of a great fiesta, and links the tragedies of Firmin and his wife, Yvonne, to the world tragedies of war and man's inhumanity to man.

On the morning of the Day of the Dead, which is to be his Day of Reckoning, Firmin staggers round his neglected garden, a symbol both of his ruined marriage and of the mutilated world. Here, he stumbles on a broken notice-board bearing the words,

> "Do you like this garden?
> Why is it yours?
> We evict those who destroy!"

These words, which are repeated at the end of the book, recall two of its central images, Eden, signifying the beauty man discovers in Nature and the beauty he creates in loving human relationships, and Hell, signifying the agony he suffers and causes others when he rejects love. Lowry suggests that man, a splendid and noble creature, must nevertheless struggle constantly to control sado-masochistic impulses, and can restrain them only when he loves others and is able to accept their love.

Lowry's own critical analysis of the book is to be found in his letter to Jonathan Cape, dated 2 January 1946.

Hear Us O Lord From Heaven Thy Dwelling Place. 1961 P. (Version edited by M. B. Lowry).

A volume of short stories and *nouvelles* includes *Through the Panama, Strange Comfort Afforded by the Profession, Gin and Goldenrod* and *Forest Path to the Spring*, which are concerned with various events in the life of Sigbjorn Wilderness, the protagonist of the unfinished Mexican trilogy.

Lunar Caustic. 1963. (Version edited by E. Birney and M. B. Lowry).

A moving and concentrated *nouvelle* begun in 1936 is based on Lowry's experience as a patient in the Belleview Psychiatric Hospital, New York.

Dark as the Grave Wherein My Friend is Laid. 1969. (Version edited by D. Day and M. B. Lowry).

Set in Mexico, the novel is concerned with a purgatorial experience of spiritual death and resurrection.

October Ferry to Gabriola. 1971. (Version edited by M. B. Lowry).

Of interest to the specialist student this undisciplined book has little appeal for the general reader.

Mary McCarthy (b. 1912).

The American journalist and critic Mary McCarthy has published seven satirical novels on the lives of American artists and intellectuals: *The Company She Keeps*, 1942 (P); *The Oasis*, 1949 (S); *A Source of Embarrassment*, 1950; *The Groves of Academe*, 1952 (S); *A Charmed Life*, 1955 (P); *The Group*, 1962 (P); *The Birds of America*, 1971. Like Simone de Beauvoir and Doris Lessing, Miss McCarthy is particularly interested in the rôle of the educated woman in twentieth-century society. Parts of her novels are very amusing, but in general they seem too cerebral and anaemic.

Norman Mailer (b. 1923).

Mailer, an American, is a journalist and film-director and the author of one book of verse as well as six novels. He sees life as a battlefield between the forces of good and evil and the motive behind the sensationalism of much of his later work seems to be a desire to shock readers into an awareness of the nature of American society, which he feels is obscene and life-denying. Mailer suggests that the majority of Americans are either becoming cogs in the machines of a brutal, totalitarian "technology land," or taking selfish refuge in drugs and nihilism, instead of accepting the dangers of living adventurously and trying to establish creative relationships. Readers interested in Mailer's social philosophy should refer to *Advertisements for Myself*, 1959; *The Presidential Papers*, 1963; *Cannibals and Christians*, 1966.

The Naked and the Dead. 1948. Pa.

Many critics feel this novel constitutes Mailer's most successful expression of his view of the human condition. He regards it as "the work of a young engineer." Its subject is the American troops' capture of a Pacific island from the Japanese, but its interest lies in Mailer's treatment of the power structure within the American force, which is presented as a microcosm of society. The mass of the troops, represented by the soldiers of one platoon, are shown as the all but helpless victims of the men of power—the fascist General Cummings and the Platoon Sergeant, Croft. Between the two groups stands the ineffectual liberal, Lieutenant Hearn.

Mailer paints a remorseless picture of the agony of the ordinary soldier's life and of the absurdity of the war, and is very successful in his treatment of the characters of Cummings and Croft. The weakness of the book lies in his characterisation of the lower ranks. These soldiers are obviously intended to represent a cross-section of American society, but, although using techniques derived from Dos Passos, Mailer gives a biographical sketch of each man in the platoon, none of them is clearly differentiated from the others.

Barbary Shore. 1951.

In this turgid allegory of the Cold War, the amnesiac Lovett finds himself involved in a contest between two secret agents, McLeod and Hollingsworth, for the affections of McLeod's wife, the promiscuous Guinevere.

The Deer Park. 1955. Co.

Mailer planned this novel as the first of eight, whose themes were to cover the whole of American life. This was the only one to be finished. Its theme is pleasure and its title comes from D'Angerville's *Vie privée de Louis XV*, which refers to "the Deer Park, that gorge of innocence and virtue in which were engulfed so many victims . . .". Mailer's Deer Park is Desert D'Or, a fictional pleasure resort near Hollywood.

An American Dream. 1965. M.

Both the title and the wild improbability of this novel's action suggest that Mailer intends it to be read as an allegory, showing the narrator, Rojack, resisting the suicidal lure of nihilism presented by the moon and then escaping from the evil forces of American society, personified

in his wife, her father, and her maid. The sexual relationships between the characters would thus have symbolic importance.

The novel has its comic moments, but its style is generally sensational and its language often highly obscene.

Why Are We in Vietnam? 1967. Pa.

D.J., an eighteen-year-old Texan, accompanying his parents at a dinner party shortly before leaving to fight in Vietnam, remembers a hunting trip he and his friend and his father took to Alaska two years before.

This scatalogical novel suggests, with a measure of success, the confused and distorted values of a society whose motto is "Go out and kill." The book is divided into alternating sections of breathless narrative and hysterical commentary, progressing at a speed which leaves the reader feeling rather stunned, but the chief impression is of the relish and gusto with which Mailer wrote the novel.

The Armies of the Night. 1968. P.

Mailer's finest work since *The Naked and the Dead*, this is an absorbing and at times highly comic reconstruction of the events of the Peace March on the Pentagon in October 1967. It is written in two sections. In the first the protagonist is Mailer himself, described objectively in the third person. In the second part we are helped to understand the motives and feelings of other marchers and the fears of the police and troops who confronted them. The book is notable for its objectivity and humour.

Miami and the Siege of Chicago. 1968. P.

A second documentary novel tells the story of the American Republican and Democratic party conventions in 1968.

Of a Fire on the Moon. 1970.

In a confessed pot-boiler, his third documentary novel, Mailer writes of the moonflight of *Apollo 11*.

Bernard Malamud (b. 1917).

Like Bellow (*q.v.*), with whom his name is often coupled, Malamud is a Jewish American. Both writers have a gift for wry comedy, but whereas Bellow is essentially an optimist Malamud takes a more sombre view of life. His heroes are born losers, presented with detached affection. Malamud's particular talent lies in the creation of ironic comedy offering a poetic image of an archetypal dilemma—that of the sacrificial victim.

The Natural. 1952. P.

The theme of the Arthurian regeneration myth is here expressed through the story of a baseball player, Roy Hobbs. A simple country bumpkin, Roy is a "natural" star, convinced of his own genius. His sole aim in life is to win recognition as "the greatest". Noticed by an old talent-spotter, Roy sets out to Chicago for a trial as a professional, but on the way he meets the beautiful Harriet, who has already shot two star athletes with the pistol she hides in her hat box! Luring him to her hotel room she now shoots Roy, wounding him in the stomach.

After many years of wandering in the wilderness, he is given another chance and joins the Knights, a professional team managed by the old Pop Fisher. The Knights are in the doldrums due to the selfishness of their leading player, Bump. Rivalry between Bump and Roy, who challenges his supremacy, results in Bump's death. Now Roy, armed with his precious bat "Wonderboy", revives the fortunes of the team, only to be struck down at the height of his triumph by the treachery of Bump's former mistress, whom the financial wizard, Judge, has encouraged to play on Roy's vanity.

Malamud cleverly reproduces the jargon of the baseball world and his inarticulate hero is sympathetically presented, but at times the realistic story is distorted to fit the demands of its theme and the result is a strained artifice.

The Assistant. 1957. P.

Here Malamud found a much more fruitful subject, the quiet tragedy of Morris Bober, an unsuccessful Jewish grocer and, of his Gentile assistant, Frank Alpine. For the sake of Bober and of the latter's daughter, Helen, Alpine, who has made many "false starts" in life, gives up what may well be his last hope of achieving material success. The novel is written with beautiful restraint and Chekhovian irony.

A New Life. 1961. FS. P.

Levin, a reformed drunkard, obtains an English post at a small state college, but eventually sacrifices his hard-won chance of an academic career for the sake of the woman he has loved.

The novel is set in the early 1950s, the period of McCarthyism. Malamud criticises the hysteria pervading American life at this time, exemplified in the academic and social atmosphere of Cascadia College, where Levin, a man of liberal principles, becomes the scapegoat of his colleagues' fears and prejudices.

A New Life is less concentrated than *The Assistant*. It contains elements of picaresque comedy and is at times very amusing indeed.

The Fixer. 1966. P.

Yakov Bok is, like Levin, a victim of hysterical feelings of national insecurity. A Jewish odd-job-man—a fixer—he leaves the Pale Settlement for Kiev, hoping to begin a new, more fruitful life, but is arrested on a trumped-up charge and endures three terrible years' imprisonment awaiting trial.

The inspiration of the novel was the case of Mendel Beiliss, a Kiev labourer arrested in 1911, and falsely charged with the ritual murder of a Christian child. Malamud says the novel is intended to stand "rather as a myth than an isolated case-study." But it lacks the compelling force of myth.

Pictures of Fidelman. 1969. P.

Parts of this book were published in slightly different forms in Malamud's collections of short stories *The Magic Barrel*, 1958 (P) and *Idiots First*, 1963 (P). It is an episodic work containing six "pictures" on the career of a would-be artist, Arthur Fidelman, who goes to Italy to study the work of Giotto, but soon abandons this project in order to make further attempts to discover where his own talent as an artist lies.

This is an uneven work, but enjoyable for its humour, which is derived as much from Malamud's style as from the ludicrous situations in which he places Fidelman. The best "pictures" are those entitled *The Last Mohican* and *Portraits of the Artist*. The latter contains an hilarious account of Fidelman as a sculptor of holes.

The Tenants. 1971.

In a condemned New York tenement, Lesser, a Jewish novelist, struggles to finish his third book, the masterpiece on which he has already spent ten years. He ignores the pleas of his old landlord, who begs him to move so that the building may be demolished and its site profitably developed. Unfortunately Lesser cannot turn an equally deaf ear to the claims of a fellow writer, Willie Spearmint, alias Bill Spear, a would-be Shakespearian genius, whom he discovers "squatting" in an adjoining flat.

Ex-gaol-bird and dope peddlar, Willie has become a member of the fanatic Black Soul Brothers, a group particularly hostile to Jews, who they see as exemplifying White exploitation of the Blacks. Lesser is fool enough to agree to read and criticise Willie's book. Even more disastrously, he falls in love with Willie's neglected mistress.

The novel is at once a highly comic portrayal of the writer's obsessive struggle with his material and a horrifying vision of the internecine relationship between sections of the Coloured and Jewish communities.

Brian Moore (b. 1921).

Born and educated in Belfast, Moore worked in the Mediterranean, and later in Poland, before emigrating to Canada, where he now makes his home.

In the '50s he published two novels, *The Lonely Passion of Judith Hearne* (Pa), and *The Feast of Lupercal*; the first a naturalistic study of a lonely spinster, the second of a shy, middle-aged bachelor schoolmaster. These two books set the tone for his next five novels, all of which present the fortunes of "ordinary and un-heroic" people and are concerned with the "celebration of failure" in a world "where man exists without belief". In each case Moore's protagonist is at once clearly individualised and convincingly representative of the common lot of twentieth-century man.

The Luck of Ginger Coffey. 1960. Pa.

Coffey, a struggling Irish immigrant in Canada, is out of work and at odds with his wife. Eventually offered a night job as a proof-reader on a Montreal newspaper (a position once held by Moore himself) Coffey supplements his meagre income by a second job collecting and delivering nappies for a laundry. A humiliating appearance in court results in reconciliation with his wife.

An Answer From Limbo. 1963.

Set in New York, the novel depicts the difficult relationship between a struggling novelist, Brendan Tierney, his ambitious American wife and his elderly Irish mother.

The Emperor of Ice-Cream. 1966.

A perceptive study of adolescence set in wartime Belfast presents the seventeen-year-old Gavin Burke struggling for family recognition of his reliability and independence. Realising that Northern Ireland cannot escape bombing by Hitler, Gavin leaves school and joins the A.R.P., to the disgust of his father, a patriotic Catholic solicitor. Friendship with the Marxist Freddy, an older member of his A.R.P. group, encourages Gavin in the literary ambitions his father scorns. But when Gavin follows Freddy's example and publicly declines to pretend to pray for safety during an air raid Sally, his Catholic girl-friend repudiates him.

This comic, but warmly sympathetic, novel remains one of Moore's finest.

I Am Mary Dunne. 1968.

The events of the story cover one nightmarish day in the life of a young woman whose two previous marriages have been so disastrous that she no longer has confidence in herself and cannot believe that her third, very happy marriage will last.

Harrassed by pre-menstrual tension, she begins to question her very identity and the nightmare grows worse when two former acquaintances seek her out and present their own, very different versions of her past life.

Fergus. 1971.

Again Moore presents a character haunted by the past. A successful novelist living in California with a girl young enough to be his daughter, Fergus is trying to raise the money for a divorce. While struggling with the problem he is visited by hallucinations of relatives and friends from his past life.

The novel is rather less successful than *Mary Dunne*, for while Mary is truly haunted by the people from her previous life, Fergus only seems intrigued by the ghosts of his. There are indications in the novel that Moore intended *Fergus* to summarise his previous books and his later work has shown him experimenting with new forms.

The Revolution Script. 1972.

A documentary novel based on the events of October 1970, when members of the Quebec Liberation Front kidnapped a member of the British Trade Delegation, James Cross, while another, unconnected group kidnapped and killed the Canadian minister Pierre Laporte. The kidnappers of Cross eventually surrendered him without winning any of their aims, only the guarantee of their own safe exile in a foreign land.

Moore was struck by the fact that, despite unprecedented publicity, the revolutionaries remained "faceless. Even in the last act of this drama . . . they still seemed shadows, figments of our imagination falling into exile and silence." Moore was stimulated to try to "bring these young revolutionaries on the stage". His combination of fact and fiction is not wholly successful but makes an exciting and sympathetic story.

Catholics. 1972.

A very short novel set in the near future presents a Catholic church which has abandoned belief in God and regards Christianity as an instrument of social revolution.

On the remote Irish island of Muck a conservative community of monks still celebrates Mass according to the Latin rite and unsolicited television publicity brings people thronging to attend. This causes grave embarrassment in Rome, where clerics are preparing for the "Ecumen" conference designed to promote union of the Christian and Buddhist churches. James Kinsella is sent from the Vatican to bring the monks into line.

While the situation Moore poses offers a humorous comment on current trends among some theologians, and also on the adaptability of the church as an institution, the interest of his novel has little to do with theology. It lies partly in the clash of personalities between Kinsella and the monks and more especially in the character of their Abbot, a man who long ago lost his own faith, as a result of witnessing the dreadful suffering of Lourdes, and has since cherished his small community's welfare while struggling to avoid his own spiritual dilemma.

The novel is written in beautifully pellucid prose and grips the reader from beginning to end.

Iris Murdoch (b. 1919).

Iris Murdoch is by profession a university don, a specialist in moral philosophy. Her recent collection of papers, *The Sovereignty of Good* (Routledge & Kegan Paul 1970), offers helpful insights to the student of her novels. In this book she questions the validity of that contemporary philosophy which depicts morality simply as a "matter of thinking clearly and then proceeding to outward dealings with other people," a philosophy whose ideal man "aims at being a 'realist' and regards sincerity as perhaps the only virtue." She remarks that this man is familiar to us as "lurking behind much that is written nowadays on the subject . . . of politics", and as "the hero of almost every contemporary novel."

To this Kantian view of morality as a matter of clear thought and rational expediency, Miss Murdoch opposes the Platonic ideal of morality as a matter of clear vision and disinterested love, of moral endeavour as the movement towards emergence from the dark cave of self-interest and self-absorbtion. Her novels may be seen as attempts to express this philosophy in artistic forms.

In one of her most recent, *An Accidental Man*, 1971, most of the action is concerned with the dilemmas facing two contrasted men, the young Anglo-American, Ludwig, and the middle-aged Austin. Ludwig refuses to fight in Vietnam and has destroyed his draft card. If he returns to America he will be imprisoned and lose all chance of an academic career. He feels assured of a successful future if he remains in England, where he has been offered an Oxford lectureship and become engaged to the pretty heiress Gracie Tisbourne. Common sense and expediency suggest he remain, but eventually, after he has been helped by Sir Matthew Gibson Grey (Austin's elder brother) to see clearly the moral issues involved in his problem, Ludwig decides to go home. Austin, the "accidental man", is a self-absorbed hysteric, who has morally destroyed himself through jealous hatred of the successful Matthew, and literally destroys other people: he runs down and kills a child—and tries to persuade Matthew to take the blame; indirectly he causes the deaths by drowning of both of his own wives, and falsely convinces himself that both women have been Matthew's mistresses. Only when he symbolically destroys Matthew, by smashing his treasured collection of jades and seducing the woman whom Matthew has always loved and is at last to marry, does Austin achieve a sense of satisfaction with life.

Matthew himself is a kind of Prospero figure and the novel ends with an allusion to Prospero's speech from Act V Sc. I of *The Tempest*, "All our revels now are ended," and with echoes of the mad Ophelia's words, quoted by T. S. Eliot at the end of *The Game of Chess* in *The Waste Land*.

As we have seen, Miss Murdoch dislikes the ethos of much contemporary fiction. Her own experiments with the novel bear some relation to Eliot's experiments in drama (*see* **I19**). Eliot sought by means of poetic rituals, to give expression to the ultimate themes of man's search for truth and the conflict between good and evil. From the time of *The Cocktail Party* he sought to embody these rituals within the conventions of the well-made play. Miss Murdoch, whose themes are not dissimilar, has tried to combine ritualistic actions with the conventions of popular fiction.

All her earlier novels have symbolic moments of vivid poetic intensity and beauty, such as the evocations of Rainborough's feelings as he gazes at a snail, in *The Flight From the Enchanter*, 1956 (P); of Dora's releasing a butterfly, in *The Bell*, 1958 (P); of fog-bound east London in *Time of the Angels*, 1966 (P). In her more recent books, however, the use of such symbols degenerates into mannerism, as in the description of Morgan pursuing a pigeon through the tunnels of Piccadilly Circus Underground Station in *A Fairly Honourable Defeat*, 1970, and, in *An Accidental Man*, the owl, symbolising wisdom, which attacks first Austin's landlady then Austin himself—he kills it with a brick!

With few exceptions, most notably the splendidly drawn Bruno of *Bruno's Dream*, 1969, Miss Murdoch's characters tend to be stereotyped, puppets manipulated in the service of her themes. Her use of names can be self-consciously literary. In *The Unicorn*, 1963 (P), the action takes place at Gaze Castle, while two "child wives" Dora, in *The Bell* and Dorina in *The Accidental Man* derive from David Copperfield's Dora.

Miss Murdoch continues to experiment with new techniques. The greater part of the bizarre *A Fairly Honourable Defeat* was written as dialogue. This was unsuccessful, for the characters lacked individual voices, so the narrative was extremely difficult to follow. However, the experiment bore fruit in *An Accidental Man*, where the vacuity of the Tisbournes' circle is comically expressed in chapters of characterless, inconsequential gossip. The rest of this novel is divided between chapters of conventional narrative and others, following the eighteenth century fashion, composed of letters.

Despite their sophisticated veneer, few of Miss Murdoch's novels rise far above the level of undemanding entertainment. Her first tale, *Under the Net*, 1955 (P), an amusing existentialist fantasy owing much to Beckett's *Murphy*, seems her most satisfying work to date. A sympathetic study of the earlier of her sixteen novels has been published by A. S. Byatt under the title *Degrees of Freedom*.

Vladimir Nabokov (b. 1899).

A Russian by birth, Nabokov came to England during the Revolution, subsequently lived in Germany and France and emigrated to America in 1940.

Translations of his early novels are now becoming available. Those he has written in English include *Lolita*, 1955 (Co), *Pnin*, 1957, (P), *Pale Fire*, 1962 (Co), *Ada*, 1969 (P), *Transparent Things*, 1973. The first of these gained notoriety among the ill-informed who imagined it was pornographic. Nothing could be further from the truth.

Nabokov is a learned writer. His humour, wit, and above all his masterly use of language, make his novels a constant source of delight.

Shiva Naipaul (b. 1945).

The younger brother of V. S. Naipaul (*q.v.*) was born in Trinidad of Indian parents. Educated at Oxford he now lives in England.

The Naipaul brothers' childhood was spent in a "very large and sprawling Hindu clan" of which their family was an impoverished branch. This early experience is reflected in both Shiva's *Fireflies* and his brother's *Biswas*.

Fireflies. 1970. P.

This extraordinarily accomplished first novel won the 1971 *New Statesman* prize. It is a vividly comic yet sad chronicle of the decay of the Khoja clan, acknowledged leaders of Trinidad's Hindu community by virtue of their "deliberate backwardness and eccentricities". The story centres on the fortunes of the Lutchman family, an undistinguished branch of the clan.

The novel's traditional form and leisured, naturalistic style are both appropriate to its theme and also necessary to its understanding, since Naipaul writes for readers unfamiliar with Hindu life in the West Indies.

The Chip-Chip Gatherers. 1973.

Chip-chip are tiny flavourless molluscs. Although a pailful will provide only a mouthful of food, people in some coastal villages of Trinidad are so poor that they live on them. Such chip-chip gatherers aptly symbolise the society of Naipaul's second prize-winning novel.

The book ends with Wilbert, son of one of the main characters, standing on the beach on the morning after his loveless wedding. His attention is caught by a beautifully weathered tree trunk, half buried in the sand. It seems like a sacrifice offered to "the gods of fertility and plentiful harvests", but they are here unknown and the sacrifice is "condemned to rot slowly on this windswept, shining beach of swooping vultures, starving dogs, chip-chip gatherers and himself." This compelling image encapsulates Naipaul's theme.

The main action of the book concerns members of two families from the Settlement, an Indian shanty town. Most of the inhabitants find the struggle to scrape a bare subsistence takes all their energy, but two adolescents seek wider horizons.

The gentle Bholai dreams of becoming a lawyer and a happy family man, but lacking the necessary

ruthlessness to achieve his aim, he succeeds only in becoming a grocer, despised by his wife and mocked by his children as he slaves to give his graceless son the education of which he was himself deprived.

From the first Bholai's friend Ramsaran rejects all thought of happiness and with "singleminded determination and harshness" seeks money and the power that money gives. Mysteriously he manages to save enough to start a transport business which he then runs and expands by lending money at exorbitant rates. He destroys his wife and reduces his son, Wilbert, to a hopeless cipher, but is himself destroyed by the predatory Sushila.

A beautiful woman who had run away from the Settlement and become a prostitute, Sushila seeks greater security as Ramsaran's mistress, only to be brought face to face with the realisation that as her beauty fades she is doomed.

Stark though its vision be the novel glints with humour and positive notes are suggested by Bholai's dignity and self-sacrifice—which enables his graceless son to go to England as a medical student—while, as Ramsaran bitterly observes, most people in the Settlement are happy enough, despite their grinding poverty.

V. S. Naipaul (b. 1932).

This most distinguished Caribbean writer came to Oxford at the age of eighteen and has since lived in England, travelling widely abroad.

The heroes of all his novels are men who seek freedom to give their lives order and significance and so, although his early work has a Caribbean setting, its themes are of world-wide interest. Naipaul began as a writer of comedy and all his novels have comic elements, but his work has become increasingly sombre in tone as it has increased in complexity and the conventional structure of his early novels has been replaced by more subtle and sophisticated forms.

In an interview published in *The Times Literary Supplement* of 30 July 1971, Naipaul spoke of how his work had been affected by the circumstances of his life, which have impressed upon him a sense of the insecurity of the individual. He believes the impression of security which he discerns in English society derives from the fact we have in some respects become an impotent colony of America. Naipaul remarks that the Colonial lives in an apparently secure, closed world. All important decisions are made by other people. Politicians in such countries have no effective power and can easily seem absurd—a view reflected in *The Mystic Masseur* and *The Suffrage of Elvira*, but Naipaul's later *Mimic Men* emphasises the sadness, insecurity and brevity of the Colonial politician's career. He is soon overthrown and exiled, becoming a stateless man. *In A Free State* develops the theme adumbrated in *Mimic Men*, that, in pursuing the power and freedom to govern our own lives, we pursue a mirage. Even as we seem to gain our end, we are brought face to face with the tyranny of our inner selves. Naipaul regards this latest novel "as a rather final statement" of his themes of insecurity and the pursuit of freedom.

The Mystic Masseur. 1957. P.

In this delightful comedy of Colonial politics, Naipaul shows the metamorphosis of Ganesh Ramsumair, an insignificant, semi-educated Indian, into G. Ramsey Muir, M.B.E., respected Colonial statesman.

The Suffrage of Elvira. 1958 P.

It was not until a few months before the second General Election in the Elvira constituency of Trinidad that "people began to see the possibilities". Neighbours' feuds, practical jokes, bribery black magic and marriage-broking all play parts in this campaign, which has an ill-omened beginning for Naipaul's endearing protagonist, Harbans, when he nearly runs over two Jehovah's Witnesses and a black dog! However, after a costly and nerve-wracking campaign, he wins the coveted seat on the island's Legislative Council.

A House for Mr. Biswas. 1961. Fo. P.

This sad story tells of Mr. Biswas's search for independence and security. Inveigled into early marriage, he finds he is expected to become a submissive appendage of his mother-in-law's enormous household. Biswas has no intention of playing this rôle, but he is not a practical man and has little formal education and no trade, so that his first two attempts to establish himself independently soon fail. At last, in his early forties, he manages to buy a house, but dies soon afterwards.

Naipaul makes us feel the dreadful tensions and frustrations of family life in overcrowded conditions where there is never any privacy, but despite its sad theme, the novel is often very funny, for Biswas is an imaginative man who delights in colourful language and has a flair for picturesque invective. His touching pride in his children's intelligence and his growing love and respect for his wife are most sensitively portrayed.

Mr. Stone and the Knights Companion. 1963. FS.

The elderly Mr. Stone is filled with despair at the prospect of his impending retirement. Then he suddenly conceives the idea that active pensioners of his firm should visit the disabled. Organising this scheme gives him new hope and vigour and although these fade the novel ends on a note of subdued confidence.

The Mimic Men. 1967. P.

Singh, the narrator of this fascinating novel, is an exiled politician from a newly independent Caribbean state. Singh analyses the events of his life, which he convincingly suggests is representative of those of all Colonial politicians. Thrust suddenly into power, they are compelled to destroy the former pattern of administration and, having no traditions to guide them, nor any experience of government, inevitably become "mimic-men".

Having told his story and come to terms with his past, Singh prepares to face his future as a "free man".

In A Free State. 1971.

At first this novel, which won the Booker prize, seems only a collection of stories, but, like musical variations on a theme, it is composed of five separate units forming a single whole.

The theme is introduced in the prologue, *The Tramp of Piraeus*, where the tramp's apparent dignity and freedom are counterpointed by the revelation of his loneliness and vulnerability.

In the first "variation", *One Out of Many*, an Indian peasant servant is taken to Washington by his employer, a diplomat. There he is at first a virtual prisoner in his master's flat, but then runs away, becoming a "free man". In the process he loses all self-respect. He mourns the happiness he knew in India.

The narrator of the second "variation", *Tell Me Who to Kill*, is a simple West Indian who idolises his younger brother Dayo, whom he is determined shall be educated and "nice". He sends Dayo to England, then follows and supports him there so that he may study. On the day the narrator realises that his brother has become not a student but a layabout, he is himself beaten up by hoodlums. Dayo then goes his own way, becomes a labourer, marries a white girl and ends a stranger to his brother, who, remembering their childhood happiness, seeks in anguish for the nebulous enemy who has "destroyed" Dayo.

The book's third "variation", comprising almost half of the whole work, is set in Africa. Here, Bobby, an Englishman, feels free to be himself. During the upheaval of a political coup, he is asked to give his neighbour, Linda, a lift home from the capital. Linda and Martin, her husband, have come to Africa seeking the status they lacked in England. Now they are contemplating moving to South Africa.

The true nature of the freedom these exiles have chosen is revealed as they gladly reach the expatriates' "compound"—its very name suggestive of a prison—whose safety is assured by an armed guard.

The brief epilogue, *Circus at Luxor*, shows poverty-stricken Egyptians exploited first by European tourists, who treat them as performing animals, then by a "circus" of Chinese visitors seeking to arouse in them a sense of anger and injustice. Pursuing the illusion of justice, the Eygptians are defeated in the war in Sinai a few months later and seen, "lost, trying to walk back home, casting long shadows in the sand."

R. K. Narayan (b. 1907).

Born in Madras, Narayan was educated there and at the Maharaja's College in Mysore, the south Indian city in which he now lives.

His first novel, *Swami and Friends*, 1935, which was highly praised by Graham Greene, introduced the imaginary town of Malgudi, which has since provided the setting of over two hundred short stories and nine more novels, including *The English Teacher*, 1945; *Mr. Sampath*, 1949; *The Financial Expert*, 1952; *Waiting for the Mahatma*, 1955; *The Guide*, 1958; *The Man-Eater of Malgudi*, 1962; *The Sweet-Vendor*, 1967.

Narayan is a master of classic English prose and his novels, at once sad yet delightfully humorous, offer an inimitable picture of the contradictions of Indian life. His best-known work is probably *The Guide*, for which he was awarded India's highest literary honour, the National Prize of the Indian Literary Academy.

The Guide. 1958.

The hero is Raju, son of a small shop-keeper. Despite warnings that no good will come of such headstrong ambition, he sets up as a tourist guide at Malgudi station. All goes well until he encounters the beautiful Rosie, a former dancer now married to the grave academic "Marco", an art historian. Raju and Rosie decide to run off together, so she returns to dancing and he becomes her manager, but ambition leads him into forgery and so to prison.

After serving his sentence he cannot lose face by returning to Malgudi, so wanders to a nearby river bank and sits down to think. A passing villager takes him for a Holy Man and Raju finds himself stuck with the rôle, which leads to unexpected and most uncomfortable consequences.

This ingenious story is constructed in alternating sections of third and first person narrative, the former describing Raju on the river bank, the latter giving his own account of how he came there.

Flannery O'Connor (1925–64).

The work of this novelist and short-story writer from the Southern States of America has a growing reputation in her own country, although it is less well known in England and has until very recently been difficult to obtain.

Flannery O'Connor published two novels, *Wise Blood*, 1952, and *The Violent Bear it Away*, 1960. She writes in a poetic, ruthlessly comic style about isolated eccentrics afflicted with religious mania, who evolve their own grotesque, fundamentalist creeds.

George Orwell (1903–50).

Orwell's post-war novels express feelings apparent in his earlier journalism.

Animal Farm. 1945. P.

The theme of this satirical fable is the futility of popular revolutions. Led by the pigs, the animals of Manor Farm evict their brutal owners. However, one of the pigs, Napoleon, gains absolute power, establishing a police state. The animals are worse off than before.

1984. 1949. P.

This grim nightmare, which Orwell wished to call *1948*—his publisher dissuaded him—develops the ideas of *Animal Farm* in a vision of a totalitarian world whose rulers exploit psychological and technological discoveries to retain and consolidate power.

As a novel it is less successful than *Animal Farm*. It has not the latter's occasional humour, and the presentation of its villain, O'Brien, is unconvincing. Raymond Williams's *Culture and Society* (P) sympathetically relates the novel to Orwell's paradoxical feelings about socialism.

Anthony Powell (b. 1905).

Powell published five novels in the 1930s. The elegance of his style and the fact that he took a comic view of upper- and middle-class society led to his comparison with Waugh.

His sixth work, *A Dance to the Music of Time*, is planned as a set of four trilogies. Eleven volumes so far have appeared: *A Question of Upbringing*, 1951, *A Buyer's Market*, 1952, *The Acceptance World*, 1955, *At Lady Molly's*, 1957, *Casanova's Chinese Restaurant*, 1960, *The Kindly Ones*, 1962, *The Valley of Bones*, 1964, *The Soldier's Art*, 1966 (all Fon), *The Military Philosophers*, 1968, *Books Do Furnish a Room*, 1971, *Temporary Kings*, 1973.

In this poetic novel Powell is clearly influenced by Proust. His narrator, Nicholas Jenkins, imagines the passage of time as a formal dance in which people appear and reappear unexpectedly and in surprising combinations. This is the novel's central image.

Jenkins, an extremely intelligent, thoughtful man, is a connoisseur of pictures and a novelist vividly aware of the limitations of our knowledge of others, even of our closest friends, and of the dangers of forming stereotyped ideas of people. He has an insatiable desire to understand what motivates human action, particularly how we are influenced by the thirst for power and by a love of adventure. Jenkins's gradual realisation of the complexity of life is expressed poetically through the references to paintings: as a young man he is usually drawn to Renaissance and Baroque works with classical subjects; as he becomes "less ascetic, intellectually speaking more corrupt perhaps," and recognises that "individuals live in different ways," that "all human beings . . . seen at close range are equally extraordinary," he refers increasingly to paintings of other periods.

The novel, whose action opens in the early 1920s, with a flashback to 1914, and has now reached the period following the second world war, contains an enormous range and variety of characters. Each volume introduces new figures.

Powell has the most sensitive ear for nuances of speech. His novel, leisurely, but never dull, contains passages of brilliant comedy.

Raja Rao (b. 1909).

Considered one of the most important Indian novelists writing in English, Rao published his first book *Kanthapura*, a story of village life, in 1938. His subsequent work consists of *The Cow of the Barricades*, 1947, a book of nine short stories, and two novels.

The Serpent and the Rope. 1960.

In this long and complex novel, whose title alludes to traditional symbols of illusion and

reality, Rao set out to express the spirit of the Hindu Brahmin's apprehension of life as a blend of legend and fact, of esoteric philosophy and earthy commonsense, of meditation and action.

The story is told by Rama, a young scholar doing research in Europe on the Cathari and the Albigensian heresy. He has married a neurotic Frenchwoman, Madeleine. Some years older than Raju, she is obsessed by Eastern religions, particularly Buddhism.

The action moves between Rama and Madeleine's home in Provence, his visits to his south Indian family and the major French and English research libraries. Factual events such as the funeral of Rama's father, the deaths of his own two children, his recurrent tubercular condition, the difficulties of his marriage and of his love for a friend's fiancée all form the background for Rama's complex philosophical and religious discussions with himself and his friends. Their topics range from Marxism and the function of monarchies to Hindu philosophy and abstruse points in the theology of comparative religion. Where the European or American novelist seeking to express a character's state of mind would use sensuous images and symbols to evoke patterns of feeling, Rao employs Hindu prayers and fables and philosophical mediations. For the Western reader the initial effect may be soporific but those willing to give time and effort to appreciating Rao's unusual style will be rewarded.

The Cat and Shakespeare, Rao's most recent novel, appeared in 1965. It is more optimistic in tone than *The Serpent and the Rope*.

C. P. Snow (b. 1905).

Strangers and Brothers—11 vols. 1940–70. P.

In the course of this sequence the narrator, Lewis Eliot, rises from humble beginnings to success at the Bar, at Cambridge, and in the Administrative Civil Service. While this is clearly not an autobiographical work, the course of Snow's own career as a scientist, don, and civil servant has followed a similar pattern.

The volumes follow no strict chronology and only two, *A Time of Hope* and *Homecomings*, are concerned directly with Eliot's personal life. The other books of the sequence are each centred on the life of one of Eliot's friends or acquaintances. The best of them all is *The Masters*, where an account of the election of the Master of a Cambridge college becomes an image of political life. The other volumes have a less perfect form and vary in quality, but all are of documentary interest.

The New Men deals with the making of the first atomic bomb and the painful decisions in which scientists were involved at that time. A central figure in *Corridors of Power* is a Cabinet minister who supports the Campaign for Nuclear Disarmament. *The Sleep of Reason*, inspired by the Moors' Murder case, is more concerned with younger members of society and their rebellion against rational values and materialistic standards.

Snow is unlikely to be numbered among the greatest writers of our century, but his novels are workmanlike and readable. Their greatest strength and also their greatest weakness, derives from Snow's detached, unprejudiced observation of people's behaviour. We feel that, like his protagonist, Eliot, he prefers some men to others, but rarely judges any of them. At times, however, this bland detachment seems too cold-blooded, as if people were little more than interesting laboratory specimens.

The Malcontents. 1972.

A novel in many ways similar to the later books of *Strangers and Brothers* presents a group of undergraduates concerned by callous exploitation of homelessness among immigrants. Discovering that some shabby, overcrowded tenements, let at exorbitant rents, are owned by a right-wing M.P., the young people plan a sensational exposure of the case.

Some threads of the plot are left hanging loose—it is, for example, by no means clear why the revelation must be made in exactly "two weeks and three days"—and the phenomenon of a young undergraduate in the '70s being the only child of poor German-Jewish refugees seems a strange anachronism. Snow's treatment of the undergraduates is in general less imaginative than his presentation of their parents, but he includes convincing sketches of an aggressively working-class youth and of a young woman desperately in love with one of the plotters.

Wole Soyinka (b. 1934). *See also* Section I.

A member of the Yoruba people of Western Nigeria, Soyinka has been a fierce critic of the Federal military government and during the Nigerian civil war he was imprisoned as a security risk.

His early work includes poetry, plays and an outstandingly powerful and original novel, *The Interpreters*, for which he won the second Jock-Campbell-*New Statesman* prize.

While in prison Soyinka covertly continued to write on tiny scraps of paper and since his release he has published a mass of poems, plays and polemical prose as well as a second novel, *Season of Anomy*.

The Interpreters. 1965. Fo.

In this original, highly enjoyable novel, Soyinka writes about a group of young Nigerian artists and intellectuals. The narrative is arranged in "solo" and "choral" sections, now reflecting the experience of individuals, now that of the group. The work has two main themes, which are expressed through complex symbols. The first is the characters' struggle to discover and express the relationship between their traditional culture and contemporary Nigerian society. The second is the need for a fearless commitment to the search for truth. Soyinka includes some highly comic episodes and sketches of dishonest and selfish people. Particularly memorable are an encounter with a German reporter, who likes to pretend he is American, a party given by the Oguazors, an ignorant, snobbish Nigerian don and his wife, and the ridiculous behaviour of Faseyi, who accuses his charming wife of behaving like "a bush-girl from a London slum". Soyinka takes a poet's delight in vivid and inventive use of words and is particularly skilful in his treatment of comic dialogue.

Season of Anomy. 1973.

A less complex novel, set in a fictitious African state, is an allegory of life during a period of corruption and terror. The action centres on Ofeyi's search for his girlfriend Iriyise, who has been kidnapped by officials of Cross State—the country's dominant region, although ultimate power is in the hands of the vicious international Cartel.

Ofeyi seeks to combat the Cartel's power by the peaceful means of education and example, but another young man, the revolutionary Dentist, believes that the forces of oppression can only be defeated by violence. The novel's conclusion suggests that both methods can play their part. While it is Ofeyi who discovers Iriyise's whereabouts, it is Dentist who effects her rescue.

Muriel Spark (b. 1918).

Although Muriel Spark had previously edited poetry magazines and published critical works, her literary career really began in 1951, when she gained first prize in a short story competition organised by the Sunday *Observer*. This success was followed in 1957 by the publication of the first of her ten *nouvelles*, *The Comforters* (P). A full-length novel, *The Mandelbaum Gate* (P) appeared in 1965, but, finding it "boring" and "too long", Mrs. Spark "decided never again to write a long book." Most of her work seems not only short but slight.

Her *nouvelles* can be divided into two groups. The first comprises *The Comforters*, 1957; *Robinson*, 1958; *Memento Mori*, 1959; *The Ballad of Peckham Rye*, 1960; *The Bachelors*, 1960; *The Prime of Miss Jean Brodie*, 1961; *The Girls of Slender Means*, 1963 (all P). These may all be enjoyed for their economy of language and precise vignettes of the absurd and grotesque aspects of life. The books are strange mixtures of comedy of manners and surrealist fantasy. In the later *The Public Image*, 1969, *The Driver's Seat*, 1970 (both P), *Not to Disturb*, 1971, and *The Hothouse By the East River*, 1973, surrealism gives way to whimsical melodrama and gothic "horror."

Some critics discern in Mrs. Spark's writing images of the world as God's novel. Certainly, the relation between the creator and his creation, between the novelist and his fiction, is a recurrent theme of her work, but she more often presents the agent as demonic than divine and her writing is preoccupied with violence and violent death, subjects she sometimes treats with naive callousness.

The early *Memento Mori* remains her most satisfying book. It chronicles the reactions of a group of elderly people to mysterious telephone calls saying, "remember you must die." Only in this book and, to a lesser extent, in *The Prime of Miss Jean Brodie* does Mrs. Spark seem to show any imaginative sympathy for human weakness. However, her work, like that of many other contemporary writers, has had a mixed reception. One of its most consistent admirers is Professor Frank Kermode. His reviews of Mrs. Spark's books may be found in back numbers of *The Listener*.

David Storey (b. 1933). *See also* **Section I.**

Storey, the most gifted of the group of neo-realistic novelists who emerged during the late 50s and early '60s, has drawn upon his experience of the conflicts engendered in working-class children given opportunities denied to their parents.

Trained as an artist, Storey, himself the son of a miner, has worked not only as a rugby footballer but as a showground-tent erector, as a teacher, and is now a highly successful dramatist, as well as the author of five novels. These show less versatility than his plays but nevertheless have much of interest to offer.

Although they are generally realistic in style and combine vivid scene-painting with first-rate dialogue, Storey's chief concern is to depict the inner lives of his characters and in his novels, as in his play *In Celebration* (*q.v.*), he seeks particularly to explore the ways in which the unthinking emotional force of working people, although it may give them an inner resilience, can also blind them to others' needs, and may make them cruelly destructive of both others and themselves.

The Sporting Life. 1960.

Themes which become more prominent in later novels are adumbrated in this book, which offers an interesting contrast to Malamud's *The Natural* (*q.v.*). In some ways Storey's most successful novel, it is told from the viewpoint of Arthur Machin, a young working man who becomes a rugby player with the town's team. It is financed by two local businessmen, who derive emotional satisfaction from this association with vigorous young working men. One of these backers gives Arthur a cushy job in his factory and Arthur goes to lodge with Mrs. Hammond, widow of a former worker in the same plant. She is suffering from acute depression. Machin generously supports the household and is eager to elicit some warm response, but although she becomes his mistress, she remains hostile and refuses to marry him. Meanwhile, he is harrassed by his parents, who feel smirched by his living irregularly with "that woman". Frustrated by her cold indifference to him and to the fact that he, now a local hero, has chosen her in preference to some younger, more attractive woman, Machin eventually leaves.

Much later he learns she is dying and spends hours by her bedside, coming to feel not only the depth of his love for her but to recognise something of how arrogantly he has treated her, as a chattel rather than a person. This new self-knowledge is paralleled by his realisation that his days as a star footballer are numbered and he can no longer count on either the adulation of the town or the support of the backers he despises.

Flight into Camden. 1960. P.

In a vivid first-person narrative Margaret, a miner's daughter, tells of her relationship with the depressed Howarth, an art lecturer from a similar background, who has deserted his wife. The affair engenders violent conflict within her family, particularly between Margaret and her dominant mother and aggressive older brother, who, though himself a lecturer in science, still lives at home and retains the attitudes and values of the parents.

Radcliffe. 1963. P.

In his most complex and ambitious novel Storey takes as his hero Leonard Radcliffe, the unbalanced son of a "peasant" mother and an idealistic socialist father, scion of an ancient line. They live at the Place, the Radcliffe family home, of which Leonard's father is now the caretaker. From time to time the house is shaken by violent tremors, caused by mining subsidence. These may symbolise the elemental passion which comes near to destroying the family.

Radcliffe, unconsciously dominated by his mother's emotional strength, seeks a complementary reassurance from Tolson, a sturdy working man whom he first meets as a schoolboy, but, although initially compliant, Tolson quickly resents Radcliffe's incessant demands, so driving him to a murderous jealousy. Meanwhile, Elizabeth, Leonard's younger sister, who has willingly been seduced by Tolson, gains confidence and dignity and bears a vigorous son.

The novel contains many fine realistic passages and some striking imagery, but its overall effect is rather turgid and melodramatic.

Pasmore. 1972.

In a complementary work to *Flight into Camden*, Storey presents a university don, son of a miner. He is in the throes of depression, caused by his failure to come to terms with the emotional demands made by his father and by the tension resulting from the impersonal quality of his new, middle-class environment, which denies him the warm recognition he has grown up to expect.

Whereas Storey presented his earlier book from the woman's point of view, he now writes from that of the man and in brief paragraphs, often consisting of a single simple sentence skilfully evokes the anguished sense of isolation accompanying depression, so that we come to understand Pasmore's feelings, even though our sympathies tend to lie with his bewildered wife, whom he suddenly and casually deserts, but expects to welcome him with open arms whenever he arrives for a brief visit. The unconscious comedy, which is the obverse of Pasmore's painful self-absorption, is obliquely but tellingly suggested in scenes such as that where he learns his wife has taken a lover and asks himself in tortured fury, "what could any man want with her?"

It seems a pity that Storey did not combine the insights of *Flight into Camden* and *Pasmore* into a single major work, instead of producing two cameos, fine though they be.

A Temporary Life. 1973.

In a puzzling novel, which seems more successful on re-reading than it does initially, Colin Freestone, an ex-boxer, speaks of his autumn and winter in a northern cathedral town.

Following a miscarriage his wife, Yvonne, wanted to be near her mother, but during the visit she fell into acute depression and has been admitted to hospital. In order to remain in the town, near her, Freestone obtains a temporary part-time lectureship at the local art college, where he takes the life classes.

Rebecca, one of his students, invites him home and he subsequently has an affair with her mother, who is attracted by Freestone's violent reaction to a gratuitous insult from one of her husband's associates.

Newman, the husband, is engaged in developing a huge industrial estate in the park of a former stately home. He invites Freestone to join his staff, which already includes an artist, an architect and an environmental psychologist. Freestone, studiously unimpressed, declines. Now Newman and his cronies have him beaten up. A second confrontation between him and these thugs occurs at Rebecca's birthday party and Freestone manages to inflict considerable damage on his opponents before being overcome by sheer weight of numbers.

Newman has already persuaded Wilcox, the art school's craven principal, to give Freestone notice, but before this can be served Freestone and Kelvin, the only lecturer of any originality on the staff, discover Wilcox's cloakroom is crammed from floor to ceiling with pilfered college property, and determine to spike the principal's guns. Kelvin gains security of tenure and the equipment and freedom he needs to develop his exciting projects. Freestone refuses to work out his notice and simply walks out, leaving Wilcox in the lurch for the rest of the term.

The novel ends with our hero cheerfully sweeping the roads and taking considerable pleasure in refusing a second offer of patronage made by one of Newman's henchmen.

Freestone's recital of this story is interposed by scenes with his wife and mother-in-law. The whole moves swiftly between vivid scene-setting, high comedy and anguished pathos, all recounted by Freestone in a dead-pan but curiously effective tone and manner.

At first we think that the book is offering a series of realistic impressions but then, as if the focus of our glasses were suddenly altered, we realise that the novel is a poetic fable and it is a measure of Storey's skill that this realisation comes with a shock of surprise.

The novel's themes centre on the question of how we may rightly distinguish between living and merely existing. Storey makes us ask ourselves what is the true function of education and what constitutes its value. He raises questions about the power of money, the importance of status and security, the meaning of sanity.

The more one considers the novel the more impressive it seems, yet one's overall feeling is that while Storey is here attempting a most interesting and exciting experiment, he has not quite succeeded in making it work.

William Styron (b. 1925).

A native of Virginia, one of the former slave states, Styron is particularly concerned with the theme of slavery as an emotional or spiritual condition. He implies that it is responsible for the immaturity, brutality, and ugliness of much American life and suggests that it stems primarily from the Americans' heritage of militant, repressive, and self-righteous Puritanism.

Styron's weakness is his tendency to illustrate rather than to explore his novels' themes and many of his characters are too cerebrally conceived, yet even in *Set This House on Fire*, his least successful work, Styron remains an impressive novelist. The architecture of his books, three of which are very long, is most skilful and all his work is illumined by a poetic gift for capturing the atmosphere of an event or scene and embodying fleeting visual impressions in vivid, precise images.

Lie Down in Darkness. 1948. Co.

The events of this novel take place on the day of Peyton Loftis's funeral, but most of the book consists of long flashbacks through which we learn about the lives of Peyton and her unhappy parents and come to understand why she committed suicide.

Styron implies that the Loftises' story is symbolic of life in the southern States and that the latter is itself a paradigm of American life in general. However, the novel does not sustain the weight of this interpretation, for although the characters arouse our pity they never attain the stature of representative tragic figures that such a theme demands. Nevertheless, this is a remarkable novel to have been produced by a writer of twenty-three. Its strength comes from Styron's gift for presenting individual scenes, illustrated in the novel's brilliant opening paragraphs and in episodes such as the account of Peyton's wedding.

The Long March. 1952. P.

The narrative of this very short book gives an account of the relationships between two Marines, recalled for service during the Korean war, with which they have no sympathy, and their Colonel, a regular officer, whose avoidance of any sign of emotion has earned him the sobriquet of Old Rocky. Here Styron writes of the slavery of military life and the corruption and brutality it engenders, but his underlying theme is the dilemma of liberals, who " born into a generation of conformists " are thus " trapped in a predicament which personal insurrection could, if anything, only make worse", and yet to acquiesce in it would be to become, " like cannibals, hardly men at all." The passion with which Styron expresses this dilemma makes *The Long March* his masterpiece.

Set This House on Fire. 1960

Themes from the previous books are here combined with a sweeping condemnation of the " moral and spiritual anarchy " of contemporary American life, but the novel remains essentially a *roman à thèse* and of the three main characters only Kinsolving, a drunken artist and ex-soldier, becomes more than a blueprint, and even so the parallels Styron suggests between him and Oedipus seem grotesquely inappropriate. Nevertheless, the novel is well worth reading for its incidental poetry. It contains brilliant evocations of the beauty of the Italian countryside and of rural Virginia, the hideousness of American cities and the langour of New York on a Spring Sunday.

The Confessions of Nat Turner. 1967.

This is an imaginative reconstruction of the life of the leader of an abortive slave rebellion. The story is told in the first person as Nat, awaiting trial, looks back over the events of his life and explains why he decided to murder his White masters. Nat himself is not a fully convincing figure, but minor characters are, and Styron is particularly successful in his portrayal of the liberal Judge Cobb, whose predicament recalls that of the marines in *The Long March.*

John Updike (b. 1932).

Updike, a novelist and short story writer from Pennsylvania, has a genuine and congenial talent for recreating the atmosphere and daily life of rural New England. His early ambition was to be a painter and he retains an artist's eye for precise visual detail, but, unlike Jane Austen, another " miniaturist " of country life, Updike seems to lack a sense of his own limitations as a novelist. He sometimes spoils his work by

decorating it with superfluous symbols and fails when he ventures outside the rural American scene which is the source of his inspiration.

The Poorhouse Fair. 1958. P.

Set in an old people's home on the day of its annual fair, this short novel creates a vivid impression of life in the "poorhouse" and of the characters of its inmates and its unimaginative and ambitious young director.

Rabbit Run. 1960. P.

At twenty-six "Rabbit" Angstrom still lives in the imaginative world of his schoolboy triumphs at baseball and flees from his responsibilities to his wife, children and mistress.

Again Updike vividly evokes the atmosphere and scenes of his story and his minor characters are convincingly sketched. The novel's weakness derives from its author's ambiguous attitude towards his protagonist.

The Centaur. 1963. P.

The prize-winning *The Centaur*, which covers two days in the lives of a schoolmaster and his son, displays Updike's greatest strengths and weaknesses. Alternating chapters of the narrative are written like those of a conventional realistic novel. They are vivid and highly comic. In the other chapters all characters are referred to by names drawn from classical myth and, apart from the two main characters, who are always referred to as Chiron and Prometheus, these names are inconsistently applied and serve merely to confuse. As Arthur Mitzner has remarked, the realistic sections of the book are so well written that they cannot be connected "in any but the most sterile and mechanical ways" with this mythological superstructure.

Of the Farm. 1965. P.

Here Updike reverts to the wholly realistic manner of his early novels to evoke the tensions which arise when Joey, accompanied by his new, second wife and her son, visits his possessive, elderly mother, who, singlehanded, runs the family farm.

Couples. 1968. P.

This is a sad comedy of the boredom of the lives of a group of middle-class couples who have "retreated" to the country, a boredom they relieve only by sports and frivolous sexual encounters, and are therefore shocked when two of their number have a serious "affair" and are repudiated by their respective partners.

As in Updike's earlier novels, the details of everyday life are beautifully captured, but here his central characters are rather flatly drawn.

Bech: A Book. 1970. P.

Like Malamud's *Pictures of Fidelman* (*q.v.*), which it palely resembles, parts of this book have already appeared as short stories. Bech, the protagonist, is a writer on a cultural tour and each chapter finds him in a different country. However, Updike seems to have taken small pains to coordinate these stories and, although parts of the book are amusing, the total impression is of a rather careless pot-boiler.

Rabbit Redux. 1972. P.

In a sequel to *Rabbit Run* Updike creates an image of the sterility and confused values of ordinary American life, where "anything goes".

He opens his story in April 1969, when the Americans were making their first landing on the moon. Reports of the moonshot's progress form a background to the story, which concerns Rabbit's new attempt to escape from responsibility. His eventual "return to earth" is signalled by his solemn declaration that an affair with a neurotic teenager, which has just ended in her death, has taught him "one thing worth knowing"—that he prefers sex to drugs. For the past ten years he has had an aversion to sex and his frustrated wife has recently deserted him, but now they are reconciled.

Rabbit's "trip" begins after his wife's desertion, when he meets the runaway teenager, Jill, and takes her home to become his mistress and the friend of his thirteen-year old son, Nelson. Soon Rabbit suspects that she may have become Nelson's mistress too, but decides not to enquire since "someone has to bring the kid along". Jill's other lover, a Black drug peddler, wanted by the police, also joins the household and Rabbit, hitherto a staunch conservative, is introduced to the world of drugs, Black Power and left-wing revolution, which he now accepts as passively as he had his wife's desertion. But his neighbours are outraged. Someone sets fire to the house, killing Jill.

The book is very long and its many sexual passages quickly pall, since Updike's only attempt to express them in anything other than the unsuitable medium of naturalistic prose, consists of a laboured parallel between coition and the docking of the space module. But while parts are tedious and banal, others, such as Rabbit's political quarrel with his wife's lover, are highly comic. There are vivid and moving sections depicting Rabbit's relationship with his ageing parents and Updike evokes the pathetic dreariness of small-town life with his usual talent for precise scene painting.

The chief weakness of the novel drives from his uncertain attitude towards his protagonist, who is generally presented with humorous sympathy. But while we are usually given the impression that Rabbit's self-absorbed and irresponsible behaviour is that of an immature and ignorant but amiable man doing his best in difficult circumstances, Updike sometimes suggests that Rabbit is intelligent enough to realise that "as a human being" he rates "about C minus". This places his behaviour in a different light, irreconcilable with Updike's general presentation of him and the book thus lacks a moral norm.

Kurt Vonnegut Jr. (b. 1922).

Vonnegut is the author of a number of "black comedies" satirising our century's preoccupation with war and violence. He is usually thought of as a writer of science fiction, but although he uses its techniques, like Huxley in *Brave New World* he employs them simply as the convenient vehicle for a novel of ideas.

His first book, *Player Piano*, 1952 (Pa) criticised not only the violence of contemporary American society, but also its materialism and its preoccupation with gadgets, by positing a future in which a piano that is actually intended to be played is almost as rare as a dodo, and to play it is regarded as a dangerously revolutionary act, striking at the roots of a society whose economy is based on the manufacture of "labour-saving" machinery.

Slaughterhouse 5, 1969 (Pa), Vonnegut's most famous, and arguably his best, novel is based on his experience as a prisoner-of-war in Dresden during the fire raid, of which he was one of the very few survivors.

His most recent work, *Breakfast of Champions* came out in 1973.

Evelyn Waugh (1902–66).

Waugh's style is elegant and his novels are often amusing, but they are generally superficial and marred by cruelty and distasteful snobbery. A popular writer of the 1930s, he published nine novels after the War.

The Sword of Honour trilogy (pub. in 3 vols., *Men at Arms*, 1952, *Officers and Gentlemen*, 1955, *Unconditional Surrender*, 1961 (all P), revised and reissued as one book 1965).

Waugh's best novel, this chronicles the experiences of Guy Crouchback during the Second World War. Crouchback welcomes the War, which he feels will give his life the direction and purpose it has lacked since his wife deserted him. The first two volumes of the trilogy give a convincing impression of administrative incompetence during the early stages of the War and are occasionally very funny, but they share the cruelty and snobbery of Waugh's other writing.

The third volume is much better. Crouchback, a cardboard figure until now, comes alive and, in a moving encounter with a refugee woman, is forced to admit he became a soldier in order to evade the difficulties of his personal life, and that he, and others like him, were as responsible as the "enemy" for the horrors of the War.

Patrick White (b. 1912).

White, the winner of the Nobel Prize for Literature in 1973, is unique among Australian novelists for the range of his cultural experience and understanding, which encompasses not only that of his own country and of Britain but also parts of Western and Central Europe.

After an early childhood in Australia, at the age of thirteen he was sent to England to be educated or, as he himself has put it, "ironed out", at Cheltenham College. However, on leaving school he at once returned to Australia and worked as a jackaroo—a lowly apprentice and general factotum—on remote sheep stations. Some idea of his life at this time may be gleaned from Chapter 2 of *The Vivisector*, where an account of the hero's visit to a sheep station of the period includes a sketch of young Col Forster, jackaroo and would-be novelist—"The trouble is I haven't yet experienced enough." We may suppose that this reflects White's own feeling at the time. Certainly he was already writing novels, although none were published.

After two or three years' sheep farming, he went back to England and took a degree in modern languages at King's College, Cambridge. He then made his home in London but also travelled, both on the Continent and in the United States. During the War, as an intelligence officer in the R.A.F., he went further afield, to Egypt, Palestine and Greece.

Finding post-war England "an actual and spiritual graveyard", White decided to "seek the stimulus of time remembered", and so returned to Australia. Together with a friend, he set up house in a, then rural, suburb of Sydney and the two young men supported themselves by market-gardening, breeding dogs and goats and selling milk.

White had apparently finished his sixth novel when he returned home. He had also written a number of plays and short stories and published a collection of verse, *The Ploughman and Other Poems*. However, much of this early work was unpublished, more has never been reprinted. For most readers without access to specialised Australian libraries White's earliest available work is, therefore, his fifth novel *The Living and the Dead*, 1941 (P), and a play, *The Ham Funeral*, written in 1947 (*Four Plays*, 1965).

The Living and the Dead is an uneven book but already displays the extraordinary fusion of visionary intensity with brilliant social comedy and satire which characterises all White's later work and springs from his perception of life's essential ambivalence.

All his novels emphasise the dual nature of reality, as both good and evil. While insight brings his characters intense joy it also involves them in great suffering, since it demands recognition and acceptance of evil in both others and themselves. Yet the overall effect of all the books except *The Solid Mandala* is positive and joyful.

In so far as it resembles any other novelists' White's work seems more akin to that of German writers, particularly Thomas Mann and Hermann Broch, than it does to any British novelist's. That is not to imply that Mann or Broch influenced him. White himself says that in his early novels he was indebted to James Joyce: "I think anyone who started writing seriously then was influenced by Joyce" and "I suppose I was influenced by Lawrence", but he believes that music and painting have had a greater effect than any writing on his work as a whole. "They have helped me to express myself. I feel . . . I'd much rather have been a painter or a composer than a writer."

It would seem he feels that while it is difficult to express one's vision truthfully through the medium of paint or music it is almost impossible to do so in words. The problem of how to communicate is a recurrent theme of his earlier post-war novels, in which even the most educated of his protagonists find it all but impossible to articulate their experiences of joy and suffering. Empathetic communion is their most reliable form of communication, although many of them try also to express their visions through painting, music or dance.

The post-war novels all present characters who are struggling for insight into the true nature of life, seeking to distinguish the "white radiance of eternity" from the multicoloured images we impose upon it. The novels often seem harshly critical of conventional Christianity, but they express an essentially religious vision and the characters' quest for the immanent and mysteriously transcendent "God above [the] God" of Christian convention reminds one of the work of the existentialist Tillich, particularly in his *Courage to Be* (Fo).

White may be said to fuse insights which other men have seen primarily in terms of either theology or of the psychology of perception. Some critics suggest that he does little more than give rhetorical grandeur to expressions of the pathetic fallacy, but a careful reading shows that he is concerned rather with an experience of the natural world, which we in a sense "create", since our vision of it is a reflection of ourselves, and yet at its most intense, the vision has a religious quality and changes us, stripping away the masks of everyday life, penetrating and releasing our essential selves.

White's visionary characters are thus stripped and seared by life. To others they may appear as "The Burnt Ones"—*Oi kaimenoi*, the poor unfortunates—but they are more likely to see themselves as "stroked by God", tried in the furnace of his love. Their acquaintances usually feel they are at best eccentric. They may seem subnormal or insane and they are generally avoided, frequently feared and attacked by other people, to whom their honesty and essential innocence, their refusal, or inability, to adopt the masks of social convention, present an intolerable challenge. In many cases the characters' "eccentricity" is emphasised by physical deformity, in essence a reflection of society's judgment of them. At the same time, by placing them on the fringe of society, if not quite outside its pale, their strangeness, whether the result of an unfortunate physical or mental abnormality, artistic talent or racial difference, frees the characters from social conventions and impels them to pursue their quests for truth and understanding: "honesty of purpose . . . is something that get overlaid by civilization, in houses by gable and portico, in man by the social hypocrisies."

In expressing his themes White deploys poetic images and symbols, including, among a host of others, such age-old figures as the Explorer, the Scapegoat and the Wise Simpleton. At the same time, each novel's pattern is determined, at least in part, by archetypal images such as those of the

Journey and the Creation and Fall, but White also exploits pictorial and musical forms. *Riders in the Chariot*, in particular, draws upon images of religious art, including the Pieta and the Deposition from the Cross, while the shape of the whole novel resembles that of an early Renaissance narrative painting. *The Tree of Man* is given a symphonic musical design and it is probable that forms analogous to other musical patterns will be discerned in White's work by readers who share something of his wide knowledge of this art.

While he uses the resonance of poetic, visual and musical images to give his novels depth, intensity and formal beauty, White embodies these images and symbols in highly individual characters and precisely realised social settings. Except for *The Solid Mandala*, each of his novels has a large cast and he presents a wide variety of social types, from inarticulate bush farmers and talented Aborigines to butterfly socialites and highly cultured central European Jews. The settings of the novels are equally varied, moving between rural and desert Australia, France, Germany, Greece and the American prairies; but White's most characteristic setting is suburban Sydney, immortalised in his creation Sarsaparilla, the scene of *The Solid Mandala* and the main part of *Riders in the Chariot* as well as appearing in most of his other novels, various short stories and the play *Season at Sarsaparilla*.

White uses this fictional suburb to exemplify his vision of the pretentions of so-called "civilised" life, which, he suggests we use to deflect and cushion us from the demands of reality. Such a life is presented variously as comic, sterile, hypocritical, cowardly, possessive and destructive. Its visual manifestations are pretentious and usually hideous. Above all, White suggests, such a life is at once cruel and pitiful. Those who suffer at the hands of the "civilised" will be destroyed if they cannot learn to love and forgive their tormentors.

The blindness and pretentions of this world are caught in moments of scintillating comedy and satire: "Uncle . . . was under the impression that foreigners only understood what was shouted at them . . ." A flute is "'A peculiar and not very suitable instrument for a young girl,' Mrs. Bonner was compelled to observe. 'If difference is desired—and there are some who are averse to the piano—there is always the harp.'" "Mrs. Goodman had never encouraged religion, as she herself was God."

In general, White's style makes challenging demands upon his readers. He takes a poet's delight in the metaphorical ambiguities of words and is a master of ironic bathos and the witty epigram. His work is uneven and, particularly in *Riders in the Chariot* and *The Eye of the Storm*, his style from time to time seems rather emptily rhetorical. Nonetheless, White is one of the most rewarding, if also one of the most demanding of contemporary writers. Each of his novels is extraordinarily complex and to attempt to give some idea of their nature in such a short article is to afford them at best summary justice.

The Aunt's Story. 1948. P.

A beautifully organised novel sparkling with comedy is said to be White's own favourite. It tells the story of Theodora Goodman, a spinster of independent means. As her name suggests, she has been given a special gift by God. It is a capacity for insight. Her sense of the dual nature of all life is also suggested by her name, as well as by her rather masculine physique.

The novel is divided into three unequal sections. In the first a family gathering after the death of Theodora's mother leads naturally into a recapitulation of the daughter's life up to this time. Its central experience has been the ungainly, sensitive girl's love for her father and for their home Meroë, a golden house set in a rose garden among volcanic hills.

In this childhood Eden, Theodora cannot distinguish between good and evil "in the sum total of the garden." Her first intimation of darkness comes when her father tells her of the original Meroë, "a dark place in the black country of Ethiopia", whose truth she at first wishes to deny, but in time it becomes a "dim and accepted apprehension lying quietly at the back of her mind. She was free to love the first," although there come "many bitter days" when her mother's cruelty "hardens and blackens the roselight."

After her father's death Theodora is exiled to suburban Sydney, where her mother buys a house, and only when the old woman also dies is her daughter free to begin the long "return to Abyssinia".

The central part of the novel, *Jardin exotique*, expresses the "fragmentation of maturity" which Theodora now suffers. Travelling in Europe she comes to the *Hôtel du Midi*, a half-way house significant of her own middle-age and of the central period of her spiritual journey as well as being literally half-way between her Australian birthplace and the American prairies where she is to end her days.

In the hotel, which houses a huddle of exotic refugees, Jewish, White Russian, Greek and American-Italian, who foregather in the frigid spikey cactus garden, Theodora experiences in herself the breakdown of European culture and a psychological disintegration. In terms of the novel this is necessary. Through her intuitive sharing of her fellow guests' lives she comes to recognise the complexity of her own nature, and, by implication, of all life, "a state of interminable being, hope and despair devouring and disgorging endlessly . . . 'How beautiful it all is' said Theodora Goodman."

When the hotel goes up in flames Theodora begins her journey home, but literally and metaphorically "goes west".

A brief coda finds her in the American prairies. Here she is overcome with a sense of her own frailty and incongruity, feeling, "there is finally no safeguard against the violence of personality". She forms "a black note" in the golden landscape. But, the intuition that "there is sometimes little to choose between the reality of illusion and the illusion of reality" leads to a sense of having returned to the perfection of her childhood home and she is placidly content to accept the "illusion" other people have of her "reality" as deranged. When the doctor comes to take her to the mental hospital she obediently puts on her hat, trimmed with a black gauze rose. "Her face was long and yellow under the great black hat, but the doubtful rose trembled and glittered, leading a life of its own."

The counterpointed images of gold and black form a *leitmotif* beautifully enhancing the novel's theme, while associated references to Ethiopia take up an image earlier suggested by the title of White's unpublished play, *Return to Abyssinia*, which is about an adolescent's loss of innocence. The image reappears in *The Riders in the Chariot*, where Mary Hare lives in a house named *Xanadu*, recalling Coleridge's poem *Khubla Khan*, with its vision of the "Abyssinian maid". To his collection of short stories White was later to give the associated title *Burnt Ones*—"Ethiopian" is thought to signify "burnt one", and in Classical times Abyssinia was thought of as a land of fire.

Such images of burning are of particular importance in White's earlier post-war novels and vividly embody his sense that visionary insight is associated with searing, refining experience.

In *The Aunt's Story* the black and gold images of cinder and flame are echoed by references to volcanic fire, by the flash of lightning which strikes the young Theodora and by the terrible hotel fire which she survives, though scarred and still "smouldering" until her final searing acceptance of the world's nature.

The Tree of Man. 1955. P.

A compelling and highly entertaining novel opens towards the end of the last century with the young Stan Parker clearing the bush to make himself a farm. It follows his story, and that of his wife Amy and their two children until the middle 1930s when the smallholding is beginning to be swallowed up in the expansion of suburban Sydney.

On one level the novel is an Australian epic, but it is also concerned to express the "mystery and poetry" of the lives of ordinary inarticulate people. Stan and Amy are strongly contrasted. Both seek illumination, but while he tries to see more clearly and is content to accept life as it is, she wants to possess life and is much more gradual in coming to recognise her own frailty. Part of the novel's distinction comes from the compassion with which White traces her decline into cross-grained old age.

The book's style is initially challenging, with idiosyncratic punctuation and many verbless sentences, which reflect the characters' inarticulate, sensuous apprehension of a life which affords little time for reading. The whole is woven into a symphonic pattern, based on the rhythms of the four seasons and the cycle of the agricultural year, expressing the underlying theme of man's creation, fall, exile and salvation.

Voss. 1957. P.

White's most perfect novel in a formal sense *Voss* is an historical tale inspired by the life of the German explorer Ludwig Leichhardt who in 1848 set out to cross the Australian continent from east to west and disappeared with all his party.

Two main characters are presented although, as in the previous novels, there is a large and diverse array of subsidiary figures. Laura Trevelyan, a highly intelligent young woman, stifled by the inanities of her comfortable middle-class home meets the German Voss, who hopes her uncle will support him in an attempt to cross the great Australian desert. The two young people, who are both seeking to explore the realms of the spirit, feel a mutual sympathy, which continues throughout the novel in experiences of intense telepathetic communion.

Voss's trials in the desert are thus set against Laura's more commonplace, but in a sense equally demanding, struggles to achieve a humble, disinterested love for the people whom her lively intelligence makes her at first more inclined to scorn. Both the social world of Laura's suburb and the desert experiences of Voss and his party are brought vividly before the reader's imagination in a brilliant fusion of comedy of manners and poetic tragedy.

The Riders in the Chariot. 1961. P.

In the opening chapter of *Ezekiel* the prophet tells of his vision of four creatures riding, enfolded in a fiery whirlwind, driven by the spirit over earth and sky, heralding the voice of God. In the novel, this image is associated with the Classical legend of the horse-drawn chariot of Apollo and becomes the unifying symbol, expressing a vision shared by four characters.

The first "rider" is Miss Mary Hare, "a small freckled thing". Even the discreet postmistress, who refuses to say that she is unusual, "cannot deny that Miss Hare is *different*." Miss Hare lives alone in the decaying splendour of Xanadu, a mansion built by her father and now set amid a tangled wilderness of shrub and tree on the outskirts of Sarsaparilla. A visionary, with an intense sensuous appreciation of the world, she is also an epileptic and probably of subnormal intelligence though this may result from her rudimentary education. A cruel childhood has made it very difficult for her to love other people.

Her complement is kindly Mrs. Godbold, whose life is a ceaseless round of caring for others. A naturally good, motherly woman, a laundress who supports her violent drunken husband and a host of children, placid, capable, above all loving, Mrs. Godbold has the resilient strength to endure all life's blows.

The other two "riders in the chariot" similarly complement each other. Dubbo, an Aborigini painter of genius lives in a shack among the Sydney slums. He meets Himmelfarb, a highly cultivated and scholarly Jewish refugee, at the engineering factory where Dubbo sweeps the floor and Himmelfarb has a menial job on the production line.

While Ezekiel speaks of "four creatures" he also refers to the "four faces" of each and we may see White's four riders as embodying the four aspects of the Jungian mandala: Miss Hare the sensitive, Mrs. Godbold the feeling, Dubbo the intuitive, Himmelfarb the thoughtful.

Towards the end of the book it becomes apparent that they are also to be understood as embodying some (by no means all) aspects of the Gospel figures Mary Magdalene, Mary the mother of Jesus, the apostle John and Jesus himself.

These mystical, psychological and religious images are unobtrusively deployed to give extra dimensions to characters who are clearly defined and wholly convincing individuals in their own right.

The novel is divided into seven parts. The first two are concerned primarily with the lives of Miss Hare and Himmelfarb. A brief third part continues the narrative, but is chiefly taken up with painting the background of life in Sarsaparilla. Mrs. Godbold is the central figure of the fourth part, Dubbo of the fifth. In the sixth the four riders come together in a tragic climax and a short final section celebrates a resurgence of creative love. Two of the main characters have died, a third has disappeared. Xanadu is destroyed, but there remains Mrs. Godbold's hut, "in which she continued to live" amid her burgeoning family.

Here, as elsewhere in his novels, White suggests that love which "bears all things, believes all things, hopes all things, endures all things" always survives. In one sense his book may be read as an illustration to *1 Corinthians* 13.

The setting of the story moves between the splendours of Edwardian Xanadu, the horrors of Nazi Germany, Mrs. Godbold's childhood home in the Cambridgeshire fens, and Sydney, with its slums, its discreet middle-class suburbs and sprawling fringe, in Sarsaparilla, where the book's main action takes place.

Critical reception of *The Riders in the Chariot* and novels which follow it has been curious. In each case the initial reaction was that the novel, although extraordinarily exciting, is inferior to White's best work. As time passes however, these later novels seem to move up into the critics' pantheon. Probably, like other major artists, White is often somewhat ahead of his time!

The Solid Mandala. 1966. P.

The mandala image implicit in *The Riders in the Chariot* now comes to the fore and governs both the form and nature of a book whose veneer is deceptively simple.

White presents two contrasted twin brothers, Waldo and Arthur Brown. Waldo's appearance reflects his mind, which is neat, small and dark. Clumsy, blond Arthur's childlike spontaneity and unselfconsciousness make some people treat him as a simpleton, but he is both thoughtful and perceptive. His attitude to Waldo, who hates and despises him, covertly attempting to engineer his death, is one of protective love—at once maternal and paternal in its nature. As Arthur himself comes to feel, in some ways he exemplifies the hermaphroditic Adam, but the brothers' lives are interdependent, inextricably entwined, like the threads of colour in one of the "solid mandala"

marbles which Arthur treasures as symbols of life's essential form.

The story is again set in Sarsaparilla, but this time White deals with a very limited section of society, although he gives his work a more general significance by its imagery, by the incorporation of literary and musical references and by allusions to the European background of the twins' parents and of Arthur's Jewish friends.

The book opens and closes with brief encounters between the brothers' neighbours, Mrs. Poulter and Mrs. Dan, who place the old men's lives in perspective. Otherwise the twins are described from their own points of view, although ironically and in the third person. As he would consider only fitting, Waldo's story is presented first, followed by Arthur's much shorter one, which, characteristically, nevertheless gives much more information about the family's history and presents incidents previously seen from Waldo's viewpoint in a very different, and generally happier, light.

Initially the book may seem unbalanced, for it is cunningly arranged to give us lifelike shocks of such force that we can hardly credit what we read. The first section offers plenty of hints of Arthur's sanity and kindly perceptiveness, but Waldo's contempt for him is so strong and so pervasive that we are apt to think of Arthur as virtually a moron, and so cannot at first accept the validity of the novel's second part, which presents him in such a startlingly different light.

The Vivisector. 1970. P.

The narrative concerns the life and career of a highly successful painter, Hurtle Duffield. The son of a laundress and her penurious scrap-dealing husband, Duffield is sold to the Courtneys, a gentle landowner and his frigidly neurotic butterfly of a wife. Their own child, Rhoda, is a stunted hunchback.

The novel's title has a multiple significance. Driven by sado-masochistic impulses, Mrs. Courtney is a fanatic anti-vivisectionist, but her treatment of Rhoda, whom she forces to lie splayed upon a backboard, prefigures the model of a tortured dog Duffield notices in the window of the National League Against Vivisection. Mrs. Courtney's treatment of Duffield himself is equally unfeeling, if more subtly cruel, and as a result, although he is later hailed as a painter of genius, he is in fact the "vivisector" of his subjects.

Only towards the end of his life does Duffield attain a truly creative vision. This happens partly as a result of his reunion with Rhoda, who loves him, more especially because he responds to the love of an adolescent girl, and most particularly because a cerebral haemmorrhage brings him a moment of intense insight into the world's beauty. Being thus "stroked by God", an experience comparable with that which earlier novels express in terms of lightning and fire, changes Duffield's attitude to other people, for whom he now begins to feel a sympathetic, if rather ironic, friendship. It is exemplified in his relationship with a humble and kindly homosexual grocer, whom he had formerly used in one of his paintings as a symbol of destructive hatred.

A most convincing "portrait of the artist" and his compulsive search for ways to express the truth of his vision, is set amid a diversity of vividly drawn minor characters as the action moves between the Sydney slums and suburbs, remote sheep stations, Brittany, London and the Greek islands.

The Eye of the Storm. 1973.

A charming and beautiful society woman, who is also a cruelly possessive and frigid mother, plays a minor part in several of White's novels. Here she takes the centre of the stage and is presented with ironic sympathy.

Bedridden and only intermittently conscious after a severe stroke, Elizabeth Hunter lies, cared for by three nurses and a housekeeper, while her elderly solicitor and man of affairs, Arnold Wyburd is always at her beck and call. It is typical of White's irony that Arnold is in another sense the solicited victim of a single affair, having once, early in his career, fallen prey to Mrs. Hunter's beauty.

She has been a spoilt and possessive charmer all her life, and remains one to the end, but now she has become conscious of her failings and regrets them, while seeking to acknowledge her attendants' care in the only way now left to her, by giving them presents and good—though caustically expressed—advice. Above all, she drives them to face the truth about themselves.

In her bedroom, where the tumult of everyday life is suspended, others therefore enter the "eye of the storm", where their weaknesses are revealed and accepted, just as Elizabeth Hunter had once literally entered such a storm centre.

Until the age of seventy, she was almost completely selfish and self-absorbed, though also greatly loved. The fortuitous experience of being alone on an island during a cyclone then brought an overwhelming realisation of her own weakness and insignificance. It also made her recognise that she was probably "responsible for the worst in people", particularly her own awful children. In the peace at the storm's centre, when the "myth" of herself as a kind of goddess has been exploded, she sees she is in fact a "flaw" in the world's beauty, and while acknowledging this moral ugliness, turns outward for the first time in her life to contemplate the external beauty which enfolds and accepts her as a part of itself.

Now again at the "eye of the storm", between her incapacitating stroke and the coming of death, she drifts between consciousness of the present and memories of the past, acknowledging her many cruelties and thankfully re-living the happy months she spent nursing her dying husband, the single truly disinterested act of her life.

The two elderly children who have come post-haste from Europe, offer a vivid contrast. Neither can bear to stay for more than a few moments in their mother's bedroom, where they are confronted by their weaknesses.

Sir Basil is a failed Shakespearean actor who fancies himself as Lear and never stops playing a part, while his sister Dorothy, the frigid, deserted wife of a French prince, takes refuge from the world behind her title and self-congratulatory reflections on her housekeeping and dress-sense. Unhappy and self-absorbed they are corroded by hatred and fear of their mother, who understands them only too well, and on whom they shamelessly sponge. They want her to die quickly, so that they can divide her money, and meanwhile plan the economy of hustling her into an old people's home.

Almost equally important to the novel are Mrs. Hunter's attendants, Sisters de Santis and Manhood, who, while being fully realised as humanly muddled individuals, also embody the qualities of serene goodness and creative sensuality which the Hunters so conspicuously lack.

The power of the novel comes not only from the skill with which White organises and presents his themes through a large and varied cast, but also from his choice of the central character and her predicament. Except in *The Tree of Man* his heroes and heroines have been people who, by character or circumstances, are unusual. There is little unusual about Elizabeth Hunter's brilliantly realised character and, apart from the fact that she can afford private nursing, her circumstances are commonplace.

Angus Wilson (b. 1913).

In *The Wild Garden*, a collection of lectures about his literary career, Wilson says that, as a

young man, he had no thought of becoming a writer. In some ways his upbringing was unusual. The youngest child by thirteen years of his middle-class parents, as a boy Wilson was spoilt, lonely and precocious, "learning about the nature of the world from [the] unhappy, pseudo-sophisticated declassé adults" who frequented the shabby-genteel hotels and boarding houses in which his parents lived. When he was fifteen his mother died and he became the "sole companion" of his raffish, elderly father, a compulsive gambler for whom he felt an "over close, intense affection". Wilson was later to portray the old man in various guises, most directly in "A Story of Historical Interest".

After graduating from Oxford Wilson took a post as a cataloguer in the British Museum's library. The work was intensely frustrating, but his emotions and intellect were otherwise engaged, in his relationship with his father and in the coterie political activities he shared with left-wing intellectual friends. Not until this "somewhat cosy" world was shattered by his father's death and the onset of war was Wilson forced to come to terms with adult life. There followed a long period of intense anxiety and depression. Emerging from this he began to write, producing his first story suddenly and "in intense excitement" one November Sunday in 1946. On subsequent weekends he wrote several more of the tales which were to appear in *The Wrong Set*, 1949 (P).

In this and his next collection, *Such Darling Dodos*, 1950 (P), Wilson portrays a deracinated middle-class which has failed to adapt to the sudden changes of the post-war world. The stories contain much lively social satire, but they also adumbrate themes which were to become more prominent in Wilson's later novels, themes relating to the dangers of immaturity and cherished illusions, to the need for honest self-realisation.

Until 1955 Wilson continued to work at the British Museum, now as deputy to the Superintendent of the Reading Room. During a month's holiday he wrote his first novel, *Hemlock and After* and later turned his hand to a play, *The Mulberry Bush*, which the English Stage Company chose to open its repertory at the Royal Court Theatre in 1956. Wilson found that he needed more time to work on this play than a holiday would afford, so he resigned from the Civil Service.

The adventurousness he showed in thus abandoning financial security is paralleled in his writing by a courageous readiness to experiment. He is no radical innovator, such as Beckett, but each of his novels shows him taking a new step, extending both his subject matter and his command of techniques.

His courage was particularly evident in *Hemlock and After* where he became the first contemporary British novelist to write frankly of homosexuality, a topic he has always treated as a normal aspect of human behaviour and as such amenable to sympathetic, comic or satiric treatment, depending on the nature of the character. This may seem unremarkable in today's climate, but few other novelists have written of homosexuality so objectively, and to publish such work in the early fifties, when *Hemlock and After* appeared, required no little courage, especially from a novelist at the beginning of his career. One recalls that Forster's *Maurice* (*q.v.*) was only published posthumously.

Wilson, who has written studies of Zola and Dickens, and is now a visiting professor of English at the University of East Anglia, is in some ways a very literary writer. Allusions to Dickens's novels are particularly common in his work. He is apt, for example, to speak of a character's "Quilpish humour", and in his latest book it is the memory of an incident from *Little Dorrit* that spurs the heroine to action during an Indian riot.

Like Dickens, Wilson has a taste for the grotesque and a delight in histrionics. *Hemlock and After*, *Anglo-Saxon Attitudes* and *No Laughing Matter* are all conceived in dramatic terms and prefaced with cast lists, while even Wilson's most reflective novels, *The Middle Age of Mrs. Eliot* and *Late Call*, from time to time exploit his histrionic talent.

Wilson himself believes that a gift for impressionistic mimicry is his "principal natural asset as a writer." Allied with his dramatic sense it enables him to create episodes of high comedy, but at times it can result in a certain posturing vulgarity for, although Wilson always treats his main characters sympathetically—if with a certain comic detachment—he cannot always resist the temptation to score off his minor figures. This trait is particularly noticeable in his early work and again in his most recent novel, *As If By Magic*.

A more serious weakness is Wilson's deployment of his mimetic gifts in the creation of vivid illusions of ugliness and cruelty, which he makes almost more painful to read about than they would be to witness, for the predominant feeling expressed in such passages is not revulsion but fascinated relish. Passages of this kind comprise so large a part of many of his books that much of his work is only tolerable in small doses. Critics such as Walter Allen have therefore considered Wilson more successful as a writer of short stories than as a novelist. However his two novels *The Middle Age of Mrs. Eliot* and *Late Call* are only rarely marred in this way and, despite such faults, Wilson is always a writer of immense vitality and ingenuity.

Like Jane Austen, whose work he greatly admires, he is a novelist with sharp eyes and ears for the foibles and follies of mankind and a gift for placing his characters in a precise, immediately recognisable social setting. He was the first novelist to observe and record the changing social climate of the post-war world and its strong contrast to the milieu of the thirties.

His early prose style was much influenced by Jane Austen, as a glance at the opening paragraphs of *Hemlock and After* will show, but a preoccupation with narrative technique and a desire to give his work a more "resonant", poetic quality has led him greatly to modify his style, and in his recent work he acknowledges a debt to Virginia Woolf, a writer he earlier had found unsympathetic.

Wilson has now developed a highly sophisticated command of narrative and his later novels demand close, attentive reading, but he is yet far from achieving his avowed aim, which is to marry a "sense of a transcendent evil and good to the fully felt social novel that the English have constructed in their great tradition."

A definite sense of values emerges from his novels. All suggest the importance of an honest and clear-sighted appraisal of one's actions and motives. They also emphasise the damage we do to others by refusing to face and, as far as possible to remedy, our shortcomings, and Wilson is particularly critical of the evils of acting from motives of pure expediency. But only in his presentation of ugliness and cruelty is there any sense of passionate feeling and, as we have noticed, the feeling is usually ambivalent. As this intense awareness of evil is not matched by any correspondingly vivid or numinous apprehension of goodness, most of Wilson's novels have a certain nightmarish imbalance. Except in *Late Call* and *The Middle Age of Mrs. Eliot* his world is not so much that of "the fully felt social novel" as of *Grand Guignol* and while his initial courage in presenting homosexual characters is wholly admirable, homosexuality seems to be given a disproportionate emphasis in his work as a whole.

In his first three novels Wilson draws upon his own experience of breakdown and is particularly concerned to explore the related themes of positive self-realisation, naive immaturity and neurotic withdrawal from life.

Hemlock and After. 1953. P.

Bernard Sands, an eminent novelist, is at the peak of his career. His last novel, the ambiguously titled *Player Queen*, has won high praise. Now he learns that the Treasury is prepared to give a grant to support his scheme for converting Vardon Hall, a local mansion, into a home for struggling young poets. He thinks " with satisfaction of his proved strength and independence ", of his " victory against authority in all the guises which the literary world could lend it." But, as Sands' immature attitude to fauthority reveals, his self-satisfaction is ill-ounded. As a husband and father he has failed and in approaching his public he displays a bullying arrogance.

His vague awareness of these shortcomings finds expression in a diffused sense of evil, which at first he particularly associates with his neighbour Mrs. Curry, a sanctimonious procuress, and with the vicious Sherman Winter, a theatre critic. Sands' own reaction to seeing a youth arrested for importuning forces him both to recognise the sadistic elements in his own character and to admit his inferiority to the detective who, in his dispassionate exercise of authority, reveals himself, in this respect, the better man.

After suffering a breakdown, Sands attempts to act more kindly and responsibly towards his family and friends, but dies before he can alter much.

The pattern of his self-discovery is paralleled in several of a host of minor characters, most notably Bernard's neurasthenic wife, Ella, his sister Isobel and his former and current lovers, Terrence and Eric. Contrasted figures include Bernard's daughter, his daughter-in-law, his drunken brother-in-law and Mrs. Craddock, Eric's mother. More dangerous are the perverted Rose, who has a penchant for deflowering minors, and the pimp Ron, and his employer, predatory Mrs. Curry. She is one of Wilson's most memorable creations.

The book is very short and Wilson had no time fully to develop his characters. Several of the subsidiary figures could with advantage have been dropped. The narrative is rather jerky, a collection of memorable episodes and set scenes, analogous to short stories.

Anglo-Saxon Attitudes. 1956. P.

Having now left the Museum Wilson had time more fully to develop the themes of self-discovery and self-deception that he had sketched in *Hemlock and After*. His new hero, Gerald Middleton, is not only brought to recognise his failings but given the opportunity to remedy them. Subsidiary figures, who are on the whole more fully realised than those in the earlier book, include Middleton's wife, Inngeborg, and members of their family, all of whom illustrate various modes of self-deception. Inngeborg is the least satisfying character, being superficially, though most cleverly, caricatured. Again, there is a large supporting cast of minor figures, some of whom seem redundant.

The archaeological background to the novel was suggested by a conversation on the Sutton Hoo ship-burial, overheard in the Museum's dining room. Wilson draws upon other aspects of his Museum career in the creation of his characters, the Cockney Mrs. Salad being modelled upon a Museum cloakroom attendant, while a collection of scholars includes some of Wilson's funniest sketches and the novel's first chapter concludes with an hilarious account of a meeting of the Historical Association.

The book is if anything rather too long and sags in the middle, but marked a considerable advance in both narrative technique and character drawing.

The Middle Age of Mrs. Eliot. 1958. P.

In a book noticeably different in tone from all his previous novels and short stories, Wilson writes of a crisis precipitated by the common experience of bereavement, and in his treatment of this subject he generally avoids the caricature and sadistic mimicry which mar his earlier work.

Two contrasted figures offer a fuller realisation of Wilson's concern with self-awareness and self-acceptance. The death of her husband and the resulting necessity to earn her own living compel Meg Eliot, a charming but superfical lady bountiful, to take stock of herself. Painfully educative meetings with a professional antique dealer and a social-welfare worker, with whom she had previously been associated, force her to realise the dilettante nature of her most absorbing interests. Other widows whom she had formally patronised as " lame ducks " offer well-intentioned, but unacceptably evasive solutions to her problems. After a period of breakdown, when she retreats to her brother's nursery garden—the implied regression to childhood is intentional—Meg begins to rebuild her life.

Her courageous, affirmative nature is contrasted with that of her brother, David, who, following the death of his partner in a homosexual " marriage " retreats further into a sterile renunciation of the world.

Minor figures are fewer in this novel and more fully integrated into the plot, while Wilson's control of narrative technique has become much more skilful and assured, although the sudden change to writing from David's viewpoint instead of Meg's, which comes two-thirds of the way through the book, is badly placed and weakens the structure. The chief defect of the novel however arises from its over-literary character and Wilson's dependence on the work of George Eliot and Henry James in the portrayal of his heroine.

The Old Men at the Zoo. 1961. P.

In an extraordinarily unpleasant Baroque satire, set in the near future, Wilson uses images of brutality and sadism to castigate the twin evils of megalomania and selfish expediency. As Jay Halito has noted, the novel owes much to Swift.

At first the narrator, Simon Carter, Administrator of the London Zoo, is more imaginative and sensitive than his colleagues. He is also far more self-aware; but as the novel proceeds, he grows increasingly ruthless and cold-blooded.

Successive directors, under whom Carter works, are obsessed with power and drive through their own schemes for the Zoo with pitiless disregard of both their colleagues and of the animals in their care, all of whom they treat as objects to be manipulated.

While Carter is initially critical of such actions, by the end of the novel he is himself behaving in the same way and busily canvassing his own appointment to the Directorship.

Late Call. 1964. P.

In his finest work Wilson again presents a character in the throes of an emotional crisis and, as in *The Middle Age of Mrs. Eliot*, the precipitating factor is a common one, this time the need to come to terms with retirement and the deprivations of old age. Part of the novel's strength comes from its treatment of this universal problem rather than the more unusual dilemmas with which Wilson faces most of his heroes and heroines.

Sylvia Calvert, an elderly woman of working-class origins has spent her married life running small boarding houses and residential hotels, while supporting her feckless husband, Arthur. An army captain during the first war, Arthur has never worked since, and as an inveterate gambler causes his wife much anxiety and recurrent financial embarrassment. On her retirement, which occurs at the beginning of the novel, the Calverts therefore have to accept the suggestion of their only surviving child, Harold, that they make their home with him.

While Arthur soon finds new drinking and gambling cronies, Sylvia, after a lifetime's responsibility, mostly in the closed world of seaside boarding houses, with their elderly patrons, now finds herself with little to do, in a household of young people and living on the fringes of a New Town, itself a young community. She had expected to take over the running of the household, as her daughter-in-law has but recently died, but her son insists that all tasks are equally shared by all (typically, Arthur ignores him).

A cruel childhood experience—recounted in a prologue—has inhibited Sylvia from forming any close relationships. Moreover, her work has made it necessary for her to live rather detachedly. Now she struggles to adjust to life at close quarters with her teenage grandchildren and the son with whom she has for many years had little contact.

Harold makes her task twice as difficult. The headmaster of a local secondary school, he is immature, dictatorial and utterly self-absorbed. When Sylvia refuses to accept a contrived and useless "job" he has invented for her he sulks like a child and welches on his promise to let her take charge of the cooking.

A weakness of the novel stems from the fact that Wilson's realisation of Harold's crassness is so effective that we find it difficult to believe he could possibly have the imagination and tact necessary to do pioneer work on the teaching of illiterate teenagers, although this, we are told, is what he is famous for.

The other subordinate characters are finely and convincingly drawn, as is the New Town setting, but the book's greatness stems from Wilson's remarkable characterisation of his heroine.

No Laughing Matter. 1968. P.

The techniques Wilson had developed in his early novels were fully exploited in *Late Call.* Now he extends his range and, taking a broader stage, presents the lives of six brothers and sisters against the changing backcloth of twentieth-century history. Five "Supporting Roles" are taken by the children's improvident parents, William and Clara Matthews, by the grandmother and great-aunt who support the family, and by Henrietta (Regan) Stoker, a Cockney domestic.

This is Wilson's most histrionic novel. Adapting the method Virginia Woolf used in *The Waves*, he divides a large part of his narrative among his six "Principal Players", the Matthews children, but these blocks of indirect soliloquies are interspersed with short passages of more conventional narrative, which set the stage, and by longer dramatic interludes. The first of these, a *Sunday Family Play*, in three acts, provides the model for later dramatisations of *The Game*, improvised scenes in which the five younger children mimic their parents, grandmother, aunt and servant, while Quentin, the eldest son, takes the role of the stern judge, Mr. Justice Scales.

The themes which preoccupied Wilson in his earlier books now appear blended and interwoven, as he shows how far, and in what ways, each of the Matthews children escapes from the handicaps imposed by their upbringing, an upbringing which is indeed, "no laughing matter".

The novel is something of a *tour de force.* Despite its length, its variety and its clearly differentiated characters, its overall effect is curiously flat. The whole book has something of the air of a coterie game, to be truly appreciated only by the initiate.

As If By Magic. 1973.

As in *The Middle Age of Mrs. Eliot*, Wilson presents his themes through a pair of contrasted characters, Alexandra, a hippy undergraduate and her godfather, Hamo, a distinguished agronomist, who has developed a number of high-yielding cereals, including a variety of rice named Magic.

In Wilson's earlier work, gardens and gardening are associated with immaturity and dogmatic, or even, as in *The Old Men at the Zoo*, dictatorial, attitudes. We may therefore deduce that Wilson intends Hamo's profession to reflect his essential immaturity and refusal to adapt himself to other's needs.

These aspects of his character are shown both in his relationships with his colleagues and, more especially, with his sexual partners. Aroused only by young men of between about seventeen and twenty, whose physical maturity parallels his own emotional age, Hamo sets out on a world tour eagerly anticipating an encounter with the "ideal youth" who has for so long eluded him. The irresponsibility of his life becomes ever more clear as we see him vainly pursuing various young men, bringing disgrace and disaster to them all. Meanwhile, he is compelled to realise that, by encouraging the cultivation of Magic without considering how it might affect indigenous agricultural and social patterns, he has been the indirect cause of thousands, if not millions, of impoverished peasants being thrown into utter destitution, while already prosperous farmers and landowners make bigger and bigger profits.

Wilson parallels Hamo's voyage of discovery by the adventures of Alexandra who, discovering that she is pregnant, gives up participation in the naïve dramas improvised by her hippy companions and, after a period of hysterical anxiety, begins to behave as a rather more responsible, if unconventional and immature, adult.

Technically the book marks another step in Wilson's continually developing narrative technique and the influence of his study of Virginia Woolf is particularly apparent in the novel's opening section, but this is also the least successful. It is told mostly from the viewpoint of Alexandra, and while Wilson writes of Hamo's world with assurance and authority, his attempts to mimic hippy jargon fall disastrously wide of the mark, and the childish inanity of Alexandra's comments is wildly at odds with Wilson's references to her high intelligence. His treatment of his heroine, though not of her boyfriend Ned, grows more assured as Alexandra emerges from hysteria and, now a mother, becomes the vehicle for his criticisms, both of the hippy way of life and of commercial expediency.

The novel contains some passages of fine social comedy, and marks an interesting development in Wilson's style, but as a whole it is disappointing and marred by spitefulness in the early stages as well as by the grossness of one of the homosexual episodes.

II. HOW TO ENJOY A POEM

References are to the *New Oxford Book of English Verse*, 1972.

Many people who enjoy listening to music and looking at pictures and sculpture find it difficult to appreciate poetry and a few suggestions as to how we may approach a poem may be helpful. Perhaps the first thing to bear in mind is that just as we cannot fully appreciate an unfamiliar piece of music at a first hearing, nor the subtle interplay of form, line and colour in a picture with a single hasty glance, so it is equally impossible to savour the full richness of a poem in the course of one or two quick readings. A writer was once looking round an exhibition of modern paintings, fascinated by their unusual colours but utterly at a loss as to their significance and inclined foolishly to criticise what he could not understand. Sitting down to rest his aching feet, he gazed at the painting in front of him. Suddenly, as if he had put on a new pair of spectacles, the picture came into focus. It still seemed mysterious, but though he still could not fully understand it the writer now began to enjoy it. In a similar way, we can "walk around" and gaze at a poem for a long time feeling more a sense of bewildered fascination than pleasure, then, suddenly, we find a clue to the poet's vision. But how shall we seek it?

When we first meet a poem it is often helpful to read it aloud for the poet makes use of the sound and rhythmical patterns of words and although the printed poem may seem flat as does a music score to the uninitiated, when heard it comes alive.

Then we must remember that a poet normally uses words not only literally but also figuratively and loves to speak of one thing as if it were another. When Keats describes the pleasure he has found in books he talks of them as if they were countries and he a traveller:

> "Much have I travell'd in the realms of gold
> And many goodly states and kingdoms seen;"
> (OBEV 562).

Another important point is suggested by Peter Porter's *Sanitized Sonnet 4*, which begins,

> "Much have I travelled in the realms of gold
> for which I thank the Paddington and
> Westminster Public Libraries:"
> (*The Last Of England*, p. 41).

A poem, even a contemporary poem, is an historical object. It has been affected by the poetry which preceded it—Porter expects us to recognise his quotation from Keats and to appreciate the new perspective in which he places it. A poet may write within, or in reaction from a particular convention: in Elizabethan and Jacobean times it was a poetic fashion to speak of women as gardens, or as if their faces shone like the sun, (OBEV 158, 164, 178, 255). A poem may be inspired by particular events and people, as are Yeats's *Easter 1916* and Dryden's *Absolom and Achitophel* (OBEV 767 and 365–366) and our enjoyment may be enhanced if we know to what and whom the writer refers. A poem always grows out of the experience of a single individual at a particular point in time. We are therefore helped to enjoy it if we know when and by whom it was written and can place it in its historical perspective.

In *The Business of Criticism* Helen Gardner quotes the case of the student who said that the poem beginning

> "At the round earth's imagined corners
> Blow your trumpets, angels,"
> (OBEV 200)

was written by a very simple man. She points out that it is indeed true that no contemporary educated Christian would use such images and we may fail to enjoy the striking originality and sophistication of the way they are employed to express a simple faith unless we know that they were conceived by a writer of the early seventeenth century and unless we have some idea of the ways in which men of that day lived, thought and wrote. We will enjoy the poem even more if we know something of the life and other work of its creator, John Donne. We can never learn too much about a poem, but always we come back to the work itself, for it exists not only as an historical object and the product of a particular mind and vision, but also in its own right, as an enduring work of art.

Making out the "Meaning".

Remembering always that the poet normally speaks in images and that the images he uses may be influenced by the particular conventions of his day, we need to give close attention to his words if we are to appreciate their full significance. I. A. Richards in *Practical Criticism* formulated certain principles which may aid one in making out the "meaning". He distinguished four kinds of "meaning": the "plain sense" of the poem, the "feeling", the "tone" and the "intention". The "plain sense" is arrived at simply by following the words, and incidentally the punctuation, in an attempt to find out what the poet actually says. Readers do not always do this. Another aspect of the "meaning" is the poet's "feeling" for his subject—does he, for instance, express awe, tenderness, anger, amusement? Then, is his "tone" towards the reader confidential, appealing or didactic? Finally, Richards speaks of the "intention" of the poem, the whole aim that the writer is trying to pursue.

Distinguishing Subject and Theme.

Another illuminating way of looking at a poem is to distinguish between its subject and its theme, for they are seldom identical. A poet loves to transpose his experience into another setting, and below his surface narrative or description we usually find a second "meaning", the theme, which is the core of the poem. Often there are many themes subtly interwoven. In *Resolution and Independence* (OBEV 484), Wordsworth writes of a spring morning walk, but the themes of his poem are many, one being his fear of failure, poverty and ignominious death. Shelley addressed an ode to the West Wind (OBEV 549) and here one of the main themes is a plea for poetic inspiration.

The Formal Aspects of the Poem.

Other pointers to its meaning are to be found in the formal patterns of the poem the metre and literary form in which it is cast (*see* Part IV), the kind of imagery or figures of speech (Part V). Just as all roses have a certain fundamental similarity so do all examples of, say a sonnet. With a sonnet, as with a rose, we can enjoy its beauty without ever knowing its species, but we better understand and relish the peculiar beauties of the example before us if we can recognise it for what it is.

Study of Shakespeare's Sonnet 73 (OBEV 143).

> That time of year thou mayst in me behold
> When yellow leaves, or none, or few, do hang
> Upon those boughs which shake against the cold,
> Bare ruined choirs, where late the sweet birds sang.
> In me thou seest the twilight of such day
> As after sunset fadeth in the west:
> Which by and by black night doth take away,
> Death's second self, that seals up all in rest.
> In me thou seest the glowing of such fire,
> That on the ashes of his youth doth lie,
> As the death-bed whereon it must expire,
> Consumed with that which it was nourished by.

This thou perceiv'st, which makes thy love more strong,
To love that well which thou must leave ere long.

Kinds of Meaning.—Searching for the plain "sense", we find here three clearly defined images, the first of very late autumn,

" When yellow leaves, or none, or few, do hang
Upon those boughs which shake against the cold ".

Then follows an image of twilight, the brief phase after the sunset has faded and before the fall of night. The third image is of a dying fire, glowing amid its ashes. All these, says Shakespeare, " thou mayst in me behold ". All three, then, suggest that phase in man's life that follows the prime, the decline towards death. The " feeling " of these first twelve lines is sombre and foreboding, and in its " tone " the poem speaks to one alone—" thou mayst behold," " thou seest ". Then when we reach the concluding couplet we perceive the " intention " of the poem. It is a love poem,

" This thou perceiv'st, which makes thy love more strong,
To love that well which thou must leave ere long."

Subject and Theme.—We can also approach the poem trying to distinguish " subject and theme ". Then we perceive more clearly the theme of the imminence of death, which gradually develops and gathers momentum. For instance, the trees are called " bare ruined choirs " where the birds no longer sing, and this suggests a ruined empty abode from which the voice has flown, the spirit departed. Then the " black night " which succeeds twilight is " Death's second self ", and the fire lies on the ashes " As the death-bed, whereon it must expire ".

The very colours of the poem are suggestive. A picture is painted in sombre greys and black, lit up by a dull glow soon to be engulfed in darkness, the yellow leaves on the bough, the sunset fading into twilight, the fire dying on the ashes. It is like the chiaroscuro of a Rembrandt painting.

Formal Pattern.—If we now attend to the formal patterns of the poem we find how exquisitely they match the sense. The poem is a sonnet (*see* M64), that is a brief lyric poem of only fourteen lines, expressing feeling in a taut and concentrated way. There is no room for digression; every word counts.

As we expect from a Shakespearean sonnet we find the rhyme scheme ABAB CDCD EFEF GG. This indicates that the poem will naturally take the design of three quatrains and a concluding couplet. Then how exquisitely and precisely each image is contained within the brief compass of its quatrain, and how apt are the metaphors in which the images are expressed.

If we now turn to another " autumnal " poem we may be helped towards appreciating the variety of ways in which a poet can use familiar material to express a personal vision.

" October Dawn

October is marigold, and yet
A glass half full of wine left out

To the dark heaven all night, by dawn
Has dreamed a premonition

Of ice across its eye as if
The ice-age had begun its heave.

The lawn overtrodden and strewn
From the night before, and the whistling green

Shrubbery are doomed. Ice
Has got its spearhead into place.

First a skin, delicately here
Restraining a ripple from the air;

Soon plate and rivet on pond and brook;
Then tons of chain and massive lock

To hold rivers. Then, sound by sight
Will Mammoth and Sabre-tooth celebrate

Reunion while a fist of cold
Squeezes the fire at the core of the world,

Squeezes the fire at the core of the heart.
And now it is about to start."

Ted Hughes, *The Hawk in the Rain* (Faber, 1957).

Kinds of Meaning.—The title serves as an initial guide—the poem is about the dawn of an October day. The first three stanzas form a single sentence. It opens with a striking evocation of autumnal warmth and colour—" October is marigold "—but ends with a suggestion of the awakening of a great ice-age: the half-empty glass of wine has " dreamed a premonition of ice . . . as if/The ice-age had begun its heave." We notice that the wine glass is gradually personified and that the vague foreboding of its " dream " remains with it now that morning has come, it has a " premonition of ice across its eye "—a glazed look. The image of the wine glass combines with the images of stanza four to suggest the morning after a lively party which has continued late into the night. The poem tells us all this is doomed. " Ice has got its spearhead into place ". We notice the warlike associations of " spearhead " and that it is a primitive weapon, but poised for the kill. There follows a description of the way the ice overpowers and imprisons first " a ripple ", next " pond ", next " brook " and then even " rivers "; then comes a startling image of the great ice-age monsters, the mammoth and sabre-tooth tiger, celebrating a " reunion " while a cold fist " Squeezes the fire at the core of the world "—as if the cruel power of the ice were penetrating even to earth's molten centre.

The " feeling " changes from one of relaxed warmth through a growing sense of menace to one of fear. The " tone " is impersonal and prophetic, quite different from Shakespeare's. Hughes is speaking of a process which may affect everyone. In his poem, as in Shakespeare's, the " intention " becomes clear only in the final couplet. It suggests that Hughes is writing not simply of the way winter encroaches upon the warmth of October, but expressing a terrible sense of the imminence of a nightmare state of psychological and spiritual winter, one in which ruthless primitive forces unite to destroy one's very life. This is the theme of the poem.

Subject and Theme.—Subject and theme thus distinguished, the significance of the poem's images becomes clearer. We notice how the aural imagery of the first six lines is used to amplify the theme. At first the vowels are long and open, the consonants predominantly soft, but the sharp penultimate syllable of premonition introduces a series of menacing hissing sounds in lines five and six. Then, as in Shakespeare, we find an image of music—" whistling " shrubbery—implying cheerful, light-hearted gaiety. The phrase may suggest a shrubbery full of whistling birds—the dawn chorus—it may also suggest cheerful guests at the party—Hughes is unspecific, perhaps because he wants us to think of both. We also notice that the sound of the word whistling here contradicts its cheerful connotations, for it subtly echoes the menacing hisses of the earlier lines.

Hughes tells us that the shrubbery is " green " to emphasise that it is full of life—green is a traditional symbol of fertility. Later he uses other symbols of life and vitality—water and fire. All will be conquered by the " ice ".

Beneath the main theme we may distinguish a subsidiary one, that of the approach of old age and death. Then we perceive that the glass of wine also symbolises life. It is spoken of as now half full—we begin to age, at first almost imperceptibly, in our prime, when we have drunk only half of life's glass.

Formal Patterns.—Turning to the poem's form, we notice that it is written in octosyllabic couplets (M 60), but that the rhyme scheme, metre and sentence patterns have been adapted so as to match and reinforce the poem's themes. We expect couplets to rhyme. These ones suggest a rhyme, sometimes almost do rhyme, yet continually frustrate our expectation and so increase the sense of unease, until in the last stanza they meet with a clinching finality all the more powerful for having been so long delayed:

> " Squeezes the fire at the core of the heart,
> And now it is about to start."

Further Suggestions: The Poems in Their Settings.—There is yet much to discover about these two poems. We will find that each time we return to them we become aware of some fresh aspect of their significance. New insights will be given if we study the poems' settings.

J. W. Lever in *The Elizabethan Love Sonnet* shows how Shakespeare took a hackneyed convention of his day and gave it new vigour. The sonnet we have read is addressed not to the poet's real or supposed mistress, as were other Elizabethan love sonnets, but is one of a series celebrating the affection between the ageing Shakespeare and his younger patron. Modern recognition of homosexuality may lead us to assume their relationship was sexual, but in Elizabethan times homosexuality was a mortal sin and when we learn more of the relation of a Rennaissance poet to his patron and of the Rennaissance ideal of Platonic friendship between educated men, we understand Shakespeare's poem differently. Further light is shed on its significance by other sonnets in the series.

The condensed elliptical style of Hughes's *October Dawn* is characteristic of twentieth-century verse. If the mode is unfamiliar to us our understanding of the poem will be enhanced by reading other modern poetry and "learning the language". We can extend our acquaintance with Hughes's poetry and learn to recognise and savour the individuality of his vigorous, sensuous style. If we read other English " nature poems " we shall be better able to appreciate and enjoy the originality of his vision.

III. TWENTIETH CENTURY POETRY

This section does not profess to be a full account of the poetry of the current century, as that would not be possible within the present compass. The aim is rather to touch upon some aspects of the poetry and to suggest ways of approaching it.

I. INTRODUCTION.

The Poem as an Art Form expressive of Feeling.

There is no short cut to the enjoyment of poetry. The only approach is an attentive reading, poem by poem, remembering always that the poet is attempting to express personal *feeling* through a pattern of words, in which their order, their associations, and their verbal music are all of the utmost significance.

Coleridge described poetry as a more than usual feeling with more than usual order, and the reader may like to turn to the paragraph on the function of dramatic art (I3) where reference is made to Susanne Langer's thesis that art gives form to our feeling response to life. By this is meant not only emotion as distinct from reason, but the whole gamut of our response to life as human beings—what it *feels* like to use the senses, to have emosions, even what it feels like to think.

Such feeling response cannot adequately be conveyed by logical discourse. How often we hear the phrases " I mean ", " You know ", from speakers who implicitly acknowledge that they are incapable of " expressing the inexpressible " through the medium of prose discourse and must rely on the sensitivity of their hearer to interpret their feeling. The artist's task is to translate the inarticulate cry into significant images, patterns and forms which convey their import with precision and beauty.

It is perhaps easier for us to see how the painter, the sculptor, or the musician can do this, and how, like Henry Moore, they may resolutely refuse to say what their work " means ", for to limit it to " meaning " is to divert attention from its unique value, its numinous feeling quality. But the poet in his subtle and difficult art must use as his material words and grammatical structures which themselves have meaning from which they cannot be divorced. Although possible meanings of individual phrases must be established, the modern literary critic eschews any attempt to state what the poem as a whole " means ". He attempts rather to " explicate " the poem, to unfold its hidden implications, to make clear its significance as a whole. We must remember first and foremost that a poet normally uses words not literally, but with a figurative meaning. He loves to speak of one thing as if it were another. The best approach is first to read the poem as a whole and then re-read it with particular attention for the special import of the individual figures of speech.

Special Difficulties of Twentieth-century Poetry.

Poetry of the current century presents the reader with special difficulties. Hitherto, however strange or elaborate the imagery, in most poems prosaic statements and a rational framework could be discerned, but from about 1910 even these were often discarded, so that an even greater receptivity is demanded of the reader.

Drastic Social Changes in the Era between the Wars.

For a fuller understanding of modern poetry we should return to the vital period between the wars, when the masters, Yeats and Eliot, were developing new insights and techniques and setting standards which have not since been equalled.

Inevitably the poetry of the time reflected contemporary changes in society. The Georgian Books of Verse, 1911–22, illustrate how the familiar rural tradition was becoming outworn and it was now to be maintained by only a few poets, Hardy being the most distinguished and influential. For England was fast becoming a predominantly urban society and the imagery of the countryside, inevitably used by Shakespeare, Wordsworth, and Keats, was becoming no longer relevant, sometimes incomprehensible to the townd-weller.

In France, fifty years earlier, Baudelaire (1821–67) had drawn inspiration from the city, both in his preoccupations and in his imagery. In England it was the genius and originality of Ezra

Pound (1885–1972) and T. S. Eliot (1888–1965), with their highly original experiments in theme and style, who now gave direction to a new kind of poetry, urban, sophisticated, and cosmopolitan.

Other social factors had their influence. The horror and futility of the First World War, the Communist revolution, the economic slump, the decline in religious faith, the discoveries of Freud, all contributed to the collapse of the old stable sureties and left poets profoundly shaken and searching for new values and effective modes of expression.

Pound, Eliot, and W. B. Yeats (1865–1939) all repudiated the current bourgeois values of wealth and worldly success, which with the rapid growth of industry, commerce and advertising were becoming ever more deeply entrenched. Stigmatised by Matthew Arnold in *Culture and Anarchy* as " Philistine " in 1869, they are the corrosives of art and cause the poet to feel out of sympathy with society.

Pound and Eliot, and later William Empson (b. 1906) consciously directed their poetry to a select minority. Intellectual and satirical, it makes no appeal to facile emotion. The familiar metres and rhymes have been discarded. The elliptical syntax, the complex organisation of the imagery, the erudite references to other cultures, all make demands. A phrase like Pound's " His true Penelope was Flaubert " is not immediately clear. Such poetry is not intended to be lapped up by a complacent bourgeoisie.

Another aspect of the new style was indifference to accepted canons of " respectability ", in subject and in diction, a candour about sex (encouraged by the work of Freud), and the use of vernacular and slang, which in the Sixties sometimes degenerated into scurrility.

Aesthetic influences.

(a) *The development of the romantic aesthetic*

One of the prime causes of the change in poetic method is not social but aesthetic, the clarification and evolution of the Romantic concept of poetry.

In *Romantic Image*, Frank Kermode has pointed out that from the time of Coleridge there has been a growing conviction in writers such as Keats, Blake, Pater, and Yeats that the artist, in whom the powers of imagination are allied with a passionate sensibility, has a special quality of apprehension and expresses his intuitions in a unique way. The work of art, according to this theory, is original, essentially whole in itself, an " aesthetic monad " and resists analysis into form and content. Without ulterior purpose or utility, its only *raison d'être* is " to be." The image, Coleridge insisted, is essentially " vital ", not mechanistic but organic, and it has itself been presented by organic images, notably that of the tree and the dancer.

(b) *The French Symbolists*

In his *Axel's Castle*, 1931, Edmund Wilson discussed the aims of the French Symbolists and their stimulus to English writers, including Yeats and Eliot.

The Symbolist leader, Stephane Mallarmé, attempted to create a new idiom for poetry. Supremely disinterested, a " saint of literature ", he wrote little himself, but at his modest weekly receptions he gently expounded his influential views to such visitors as Whistler, Degas, Laforgue, Valéry, Claudel, Gide, Wilde, George Moore, Yeats, and Debussy.

Influenced by Poe, Mallarmé cultivated in his poetry a suggestive indefiniteness, blurring the distinctions between the actual world and that of dream and reverie. Debussy's well-known translation into music of his *L'Après-midi d'un Faune* wonderfully conveys his evocative and amorphous imagery.

Like Poe, the Symbolists were much concerned to reproduce in their poetry the flow of music and they were much influenced by Wagner. They came even to discard the classical Alexandrine and to develop *vers libre*. In the cult of indefiniteness they would, like Poe, confuse the perceptions of the senses. Poe, for instance, " hears " the oncoming of darkness.

What was the purpose of these experiments in poetic language? The Symbolists were so much preoccupied with the unique quality of individual experience, and with the complex and evanescent nature of consciousness, that they eschewed anything so commonplace as a description or statement as a falsification of experience and endeavoured, instead, to express unique and transitory feelings by suggestive images and symbols fastidiously chosen and patterned with exquisite care. The time-honoured rational framework of poetry was being scrapped so that it was becoming irrelevant to speak of the " meaning " of a poem.

(c) *The problem of objective validity in symbolist art*

The symbolism was not of the commonly accepted kind, such as the dove with the olive branch. Each poet deployed a highly idiosyncratic symbolism peculiar to himself in order to express his own intensely personal feelings. Such symbols were, says Wilson, really " metaphors detached from their subjects ". Inevitably such poetry is not easy to interpret. An example easily available in English is Valéry's *Le Cimitière Marin*, translated by Day Lewis as " The Graveyard by the Sea ".

The basic problem for the Symbolist poet is to find an imagery both true to his own unique experience and also in some way significant and communicable. That is the supreme test.

It is fascinating to see how English poets, such as Yeats, Eliot, and Sitwell, stimulated by the French experiments, tackle this problem and give objective validity to an intensely subjective vision.

II. SOME INDIVIDUAL POETS.

1. The Masters of the Decade between the Wars.

W. B. Yeats (1865–1939).

References are to the *Collected Poems* (Macmillan).

Yeats's influence is exerted not by the limp romantic Celtic twilight verses between 1889 and 1904 but by the complex, sinewy poems appearing between 1910 and 1939. Although in traditional verse forms they establish Yeats as a great master of the modern symbolic image.

Brought up by a father of sceptical mind, Yeats had sought from early youth for some significance to life in " heterodox mysticism ", such as theosophy and the Kabbala, and above all in Blake. Their highly developed systems of symbols stimulated his innate sensitiveness to this intuitive form of insight and expression and encouraged him to develop his gift for waiting on images as they arose from the deeper regions of his mind. Arthur Symons, whose *The Symbolist Movement in Literature* was published in 1899, introduced him to the work of Mallarmé and other French Symbolists, and confirmed him in his poetic approach which he now realised was part of a European movement.

To give objective validity to highly subjective images he used several techniques. Following Shelley's example, he would repeat the same symbol throughout the body of his work, so that one poem illuminates another. The symbol thus seen in perspective reveals new facets of its significance, sometimes even contradictory aspects.

For example, in early poems the rose signifies not only love and, in its Rosicrucian form, a mystic union, but also Ireland, beauty both sensuous and intellectual, and the beauty of Maud Gonne, with whom Yeats remained hopelessly in love.

A ruined Norman tower which Yeats had converted into a dwelling recurs from 1919 in many poems. Its basic significance is the artist's isolation, but it also suggests Milton's Platonist, Shelley's "visionary prince", Samuel Palmer's "lonely light", and Yeats's own Anglo-Irish heritage. He was greatly concerned to give the symbol solidity and firm outline and stresses the tower's emblematic "winding, gyring, spiring treadmill of a stair" and the "grey stone fireplace with an open hearth" and the "fire of turf" of simple hospitality.

He juxtaposed exalted symbols with the singularly down-to-earth motifs which he deployed with increasing frequency. The indignity of age is "a sort of battered kettle at the heel," or "a tattered coat upon a stick" until in his emblematic protagonist, "Crazy Jane," he presents the ultimate in physical destitution inspired by poetic frenzy.

Yeats also relied on archetypal images from the "Great Memory," to which we respond unconsciously. In *The Two Trees* (p. 54), he follows Blake in his use of the image of the tree, which develops from the Kabbala and the Biblical Tree of Life. To Yeats it came to embody the organic nature both of all life and of the imagination, or reality intuitively perceived by the artist as whole and vital. Yeats, like Blake, contrasted this imaginative vision with the abstractions of the discursive intellect and his most perfect expression of the work of art as an organic and indissoluble unit occurs at the climax of *Among School Children*. Here in a passage of multiple import he marries the image of the tree to that of the dance.

"O chestnut-tree, great-rooted blossomer,
Are you the leaf, the blossom or the bole?
O body swayed to music, O brightening glance,
How can we know the dancer from the dance?"

Yeats's poetry was also supported by a framework of mythology, whether of Gaelic legend, Greek mythology, as in *Leda and the Swan*, or, as in much of his more mature work, that of his own private system, which he expounded in his prose *A Vision*, 1926. For instance, he saw history as opposing cycles of 2000 years, each cycle being a reversal of the previous one. He represented this diagramatically by opposing "gyres", his gyre being the spiral traced on a cone.

But Yeats's finest poems, even when the meaning depends on his private hinterland, are still valid and intelligible in themselves. *The Second Coming* affects us through the singular clarity and force of the metaphors and the controlled energy of the rhythm:

". . . somewhere in sands of the desert
A shape with lion body and the head of a man,
A gaze blank and pitiless as the sun,
Is moving its slow thighs, while all about it
Reel shadows of the indignant desert birds.
The darkness drops again; but now I know
That twenty centuries of stony sleep
Were vexed to nightmare by a rocking cradle,
And what rough beast, its hour come round at last,
Slouches towards Bethlehem to be born?"

Yeats is the poet of paradox and often quoted Blake, "Without contraries there is no progression." His own life was one of manifold tensions, especially between contemplation and his active participation in Irish politics and art. (He was Production Manager of the Abbey Theatre and was made a Senator.)

A dominant theme is the dichotomy between sensuous living and the creation of immortal works of art, the latter symbolised by Byzantium in two splendid poems. Here he rejects the "sensual music" of "whatever is begotten, born, and dies" or "the fury and the mire of human veins" for "monuments of unageing intellect," symbolised by Byzantium, with its gold mosaic, the starlit or the moonlit dome and the golden singing bird, a miracle, "in glory of changeless metal," (pp. 217, 280).

Yet in the contemporary *Dialogue of Self and Soul*, p. 265, the poet opts for life, however sordid.

"I am content to live it all again
And yet again, if it be life to pitch
Into the frog-spawn of a blind man's ditch,"

Paradoxically the splendour of Yeats is the unresolved conflict. In poem after poem he passionately faces his dilemmas, personal, political, artistic, metaphysical, never to rest in a complacent final solution but forging instead enigmatic and arresting images of universal experience.

T. S. Eliot (1888–1965).

The poems referred to are contained in *Collected Poems 1909–1962* (Faber).

Eliot, by some years the youngest child of his American parents, grew up in the town of St. Louis, on the Mississippi River. The family also had a house on the New England coast, at Cape Anne. Here, the young Eliot spent his summer holidays. Many of his most vivid lines and images derive from memories of these childhood scenes. It is through the dingy backstreets of St. Louis that Prufrock makes his way to the drawing room where the local bourgoisie talk vapidly of Michelangelo. The river of *Dry Salvages*, whose rhythm was "present in the nursery bedroom" is the Mississippi and the Dry Salvages themselves, rocks off the coast of Cape Anne. But we do not need to have seen the Mississippi to feel the force of the river which pulsates through the lines of *Dry Salvages*, nor to have seen "the ragged rock in the restless waters" to appreciate its significance as an image of abiding agony. Similarly, although Eliot was scholarly and exceptionally well-read, familiar with several languages, it is not essential that we share his scholarship in order to enjoy his poetry, any more than we need to share Milton's or Pope's knowledge of the Classics before enjoying their work, but our appreciation is greatly enhanced by some knowledge of the sources of their inspiration. Eliot draws particularly upon his reading of Dante, Shakespeare, Jacobean literature and the anthropological work of J. S. Fraser and Jessie Weston. The interested reader will find other suggestions to pursue in B. S. Southam's *A Student's Guide to the Selected Poems of T. S. Eliot*.

In Eliot's poems unity is achieved not by a framework of narrative or sensory description or even a logical sequence of thought, but by imaginative association where several layers of thought and feeling are fused. Like Milton, he is a poet who needs to be read aloud, for much of the import of his verse is expressed through its infinitely varied music.

Eliot gives his intensely subjective vision general significance by appealing not only or primarily to the literary experience of the educated, but to the general experience of twentieth-century man; to a sense of the futility and horror of the city's "strained time-ridden faces" in streets where "men and bits of paper" are "whirled by the cold wind", images counterpointed by others of delicate beauty, evoking life's rare and unaccountable moments of ecstasy and insight,

"Whisper of running streams and winter lighting.
The wild thyme unseen and the wild strawberry".

There were two decisive influences upon Eliot's poetic development. The first was his discovery of the French Symbolist poets, to which he was led in 1908 by his reading of Symond's *The Symbolist Movement in Literature*. The other was his meeting with Ezra Pound in 1914. Pound not only helped him to find publishers for his work, but provided the stimulus of a discerning, critical audience.

Eliot's first book of poems, *Prufrock and Other Observations* appeared in 1917. The title poem offers a good introduction both to Eliot's allusive, kaleidoscopic style and to themes and attitudes which reappear in his later work. Although *The Love Song of J. Alfred Prufrock* is a dramatic monologue owing something to Browning, it

offers no clear discursive framework to guide the reader, who is required to respond to shifting scenes and moods which cohere by force of the feelings inherent in them.

The poem's title suggest something at once conventional and rather comic, while the prefactory quotation from Dante's *L'Inferno* leads us towards the poem's profounder implications. The character of Prufrock's city and of his own life is established immediately through a startling image of suspended animation—

". . . the evening is spread out against the sky
Like a patient etherised upon a table".

The correlation between the exterior scene and Prufrock's interior state is made more explicit as he and "you"—possibly the reader, possibly a young woman—make their way through a maze of sordid streets

". . . that follow like a tedious argument
Of insidious intent
To lead you to an overwhelming question . . ."

a question which is at once the proposal of marriage Prufrock dare not utter and a question of the very significance of his life and that of the social circle in which he moves.

Images of loneliness, futility, sensual attraction and suspended animation appear throughout the poem. The city is shrouded in fog and yellow smoke, at once sensual as a cat and yet stifling, suggestive of Baudelaire's Unreal City. "Lonely men in shirt sleves" lean out of windows at dusk. The afternoon and evening sleep "smoothed by long fingers".

Prufrock attends a party, feeling at once nervously self-conscious, ready to run away, "I have seen the eternal Footman hold my coat, and snicker," and yet also complacent, "My necktie rich and modest, but asserted by a simple pin". He imagines himself as a modish gallant, the cynosure of all eyes, but wryly admits, "I am no Prince Hamlet". Nor is he a John the Baptist, fearlessly expressing a vital message, but a Lazarus who has not experienced the miracle of resurrection and who therefore cannot "tell you all". He has heard the bewitching song of the mermaids, "But I do not think that they will sing to me." He can only envisage himself walking, in "white flannel trousers" upon the margin of the vital sea of life and love. Drifting into a dream of sensuous bliss "we" are suddenly woken by the deadly voice of his everyday world and "drown."

The same loneliness and sense not only of failure but of there being nothing worth succeeding in, is expressed in *Gerontion* which Eliot considered publishing as a "prelude" or preface to *The Waste Land*. This meditation on approaching death is inconclusive.

"I would meet you upon this honestly",

but if the speaker is not sure what death means he is even less sure of the meaning or value of human life. The references to "windy spaces" (line 15) and

"Gull against the wind, in the windy straits"

suggest Claudio's speech on the terrifying prospect of existence after life has ended, in *Measure for Measure*. The quotation at the head of *Gerontion* comes from the Duke's speech in that play when he tries to steel Claudio's nerve for his coming execution by proving that life is not worth having. Eliot's Old Man seems to agree, but the Duke's Christian assurance, for he is disguised as a friar, evokes no response in him for Christ, the Word, cannot communicate through the swaddling darkness. Whatever the crucifixion may have once meant has been adulterated beyond recognition and there is nothing to replace it.

The *Waste Land*, published in 1922, established Eliot as a major figure on the contemporary scene. Some reviewers thought it a literary hoax because of the elaborate use of allusion and quotation in several languages as well as the lack of any formal structure. But Sir Robert Birley has said how exciting he and his contemporaries found the poem, "no other . . . written in my lifetime has made so great and immediate an impact . . . here was someone who could give expression to our own deep, but hardly understood, doubts and uncertainties and do this in language of unforgettable beauty." Eliot himself dismissed his poem as simply "the relief of a personal and wholly insignificant grouse against life." The recent publication of the original manuscripts of *The Waste Land* together with the comments of Pound and of Eliot's first wife, Vivien, and his own alterations to the drafts, give fascinating insight into the way this "piece of rhetorical grumbling" was pruned of its purely personal elements and the private vision transformed to express "the plight of a whole generation."

The poem impresses one with a sense of disillusion and anti-climax. The old pre-war Edwardian world has been destroyed, perhaps it was never very satisfactory, but there seems to be nothing to replace it. The theme is repeated at intervals throughout, in different ways; sometimes as a dead land where the sun beats, a place where the cisterns are empty, the wells exhausted, an empty chapel with dry bones. The crowds on London Bridge walking through the fog are dead, for each is locked within himself. The modern Cleopatra seated in her burnished chair is surrounded by erotic symbols, but the romantic suggestion of the gold Cupidon is disturbed by *synthetic* perfume and destroyed by recollection of the rape of Philomel. This "Cleopatra's" life is pointless and unreal; she can only look forward to a game of chess. At the other end of the social scale there is the prostitution of personal relationship to the level of having a "good time" and instead of new life, abortion. "The nymphs are departed" indeed.

But at the end there is perhaps some hope in

"The awful daring of a moment's surrender
Which an age of prudence can never retract".

In 1927 Eliot became an Anglican. His poems, *Ash Wednesday*, *Journey of the Magi*, *A Song for Simeon*, reflect his new belief and his gift for using allusion is directed towards Christian sources. Thus in *Ash Wednesday* single lines from well-known prayers and responses from the Ave Maria and The Reproaches of the Catholic Good Friday service are used technically in the same way that the repeated and echoed phrases in earlier poems are used to give unity; and as the phrases that Eliot uses are ones that are frequently repeated in the liturgy of the church, the poem provides, for some readers, a kind of ceremony, but this peculiarly Christian imagery excludes others. The generally accessible and most successful parts of the poem are not direct expressions of Christian experience but haunting, dream-like images,

"Lady, three white leopards sat under a juniper tree
In the cool of the day"

and the expression of general human desire such as that for absolution and a tranquil mind,

"Teach us to care and not to care
Teach us to sit still".

Eliot's major work after this is *Four Quartets*, where he is concerned with the philosopher poet's experience of time, language and salvation. Helen Gardner has remarked how, whereas *Ash Wednesday* moves from personal experience to "the ageless prayer of the church," in *Four Quartets* the non-Christian and Christian experiences "suddenly touch . . . we see that what the poet has been speaking of is what Christians speak of in another language." These poems, unlike *Ash Wednesday*, give *generally* meaningful expression to human experience.

Four Quartets are full of paradoxes and though a progression of thought may be traced in the four, each Quartet may be read as a unity in itself. The mood of the second Quartet, *Easter Coker*, is sombre and the fear of nothingness, the dissatisfaction with the "shabby equipment" of contemporary language recalls parts of *The Waste*

Land; but the fourth, *Little Gidding*, named after the home of a seventeenth-century community of Anglican mystics, is more hopeful

" All manner of thing shall be well."

Considerable time needs to be spent on these poems if the complexity of the thought is to be appreciated, but the pattern of the verses, the delicate manipulation of the metre may be enjoyed by the reader who is prepared to listen carefully.

2. Edith Sitwell (1887–1964).

In *The Scarlet Tree* Sir Osbert Sitwell vividly describes his sister's early background. She was saturated in English poetry, read Baudelaire at the age of seventeen and her governess, Helen Rootham, translator of Rimbaud, became her life-long friend.

Sitwell interprets her early verses in *Façade*, 1922, as " abstract patterns in sound " written in reaction against " rhythmical flaccidity " and " verbal deadness. " She experimented indefatigably with the effect on rhythm and speed of subtle and elaborate patterns of rhyme, assonance and dissonance, successfully capturing dance rhythms. Some verses were set to music by Walton and accompany the well-known ballet.

Like the French Symbolist writer de l' Isle Adam (author of *Axel*) Sitwell also deliberately juxtaposed words that " clash in a protesting combination ". She adopted the synaesthesia practised by Poe and the French Symbolists, transferring the language of one sensation to indicate the experiences of another, as when morning light appears as " creaking " or " whining ". In later poems we find such phrases as " the dust brays ", or " purple perfumes of the polar Sun ", repeated from Rootham's Rimbaud.

Elegant and mannered, the butterfly verses of *Façade* lack inner significance yet they gave Sitwell the expertise to express intense feeling in her later poetry.

Gold Coast Customs, 1929, is the counterpart of Eliot's *Waste Land*. Both express the poet's revulsion from modern society by finding an objective parallel in primitive ritual. Sitwell, writing during the Depression, was most dismayed by the heartlessness of the city, which she images through the bygone Customs in Ashantee, where once at the death of an important person hundreds of the poor were butchered that their blood might lave his bones. This " Reeling appalling/Cannibal mart " symbolises the contemporary sacrifice of the poor demanded by the spiritually dead, epitomised by Lady Bamburger, " smart plague-cart ", massively indifferent to the destitution of the slums, where driven by " Want, a cruel rat gnawing there " the pathetic prostitutes, " The calico dummies/Flap and meet ".

The ghastly Customs, the desolate slums violently alternate and reflect each other in the kaleidoscope of nightmare, relentlessly maintained by the rhythm of savage drum beat and fevered pulse.

Although the metre and repetitive phrasing have an obsessive monotony, the impact of the poem which foretells " the sick thick smoke from London burning," is unforgettable.

In *Street Songs*, 1942, Sitwell was in command of images of arresting clarity. Two poems on the Raids are incidentally a clear vindication of Symbolist technique for both are extended " metaphors detached from their subjects ".

In the ironic *Lullaby* of despair the Pterodactyl, " the steel bird " which " fouls its nest ", has devastated the earth and only the Baboon is left to mother the surviving child.

Still Falls the Rain boldly uses the superbly simple image of rain, heavy reiteration, and a thudding, tolling rhythm, stressing the dark monosyllables:

" Still falls the Rain—
Dark as the world of man, black as our loss—
Blind as the nineteen hundred and forty nails
Upon the Cross."

It is a poem of profound and universal compassion for man and beast and also of religious faith, for the Rain is also Christ's blood shed in suffering, love and illumination.

In later publications Sitwell develops the long ode written from the vantage of the poet-seer matured by suffering. Like Yeats she was now giving her work coherence by playing variations on key symbols. Some images appear strained but the most effective are drawn from familiar sources, as the Bible, history, myth and mankind's most primitive experiences—of sun, earth, beasts, grain, fruit, metals, and of cold and warmth, always emblematic for her of evil and good. On these she sets her idiomatic stamp.

She constantly opposes two kinds of gold. In *Harvest* she celebrates the warm gold of the " laughing heat of the Sun " and " the ripe-bearded fire/Of wheat," reflecting divine energy and love. In *The Song of the Cold*, 1945, she laments the lust for the cold, destructive metal that possesses Dives and " the saints of Mammon," who " ache with the cold/From the polar wastes of the heart", the cold of hell.

Deeply shaken by Hiroshima, Sitwell wrote *The Shadow of Cain*, 1947. The theme of the title poem is fission and envisages Mankind's migration into the Cold, from Cain's first murder up to Hiroshima, when " the Primal Matter/Was broken," and " to the murdered Sun a totem pole arose of dust in memory of Man." The crisis stirs an obscure prescience of impending calamity, of a profound fission between the two aspects of Man: Lazarus embodiment of gold corn and human suffering and Dives of money and defilement. But the two golds fight and finally unite in a new resolution and hope.

This visionary poem is sometimes declamatory and the bleak *Dirge for the New Sunrise*, with its terse antitheses, is more immediate and moving.

After *The Shadow of Cain*, " haunted ever by the shadow that fell on Hiroshima," she yet continued to write poems that are " hymns of praise to the glory of Life."

3. Some Poets of the Thirties.

Wystan Hugh Auden (1907–73).

Auden was educated in a small public school, Gresham's, and later went to Oxford. Here he met Stephen Spender, Louis MacNeice, and others who formed temporarily a group of " political " poets most of whom were involved in the Spanish Civil War.

His first book of poems appeared in 1930 and was well received. After the publication of *The Ascent of F6*, a play which he wrote in collaboration with Christopher Isherwood, he was expected to become a major figure in English poetry. However, later books of verse were less well reviewed and in the mid-thirties the *Scrutiny* critics complained of his triviality, irresponsibility, and lack of maturity. Between 1939 and 1972 he made his home in America and Austria. As Eliot took out British citizenship Auden took out American, and, again, like Eliot, he accepted Christianity though perhaps in a less orthodox form.

Auden's interest in politics and the violence of political struggle is reflected in much of the imagery he uses as well as more directly in such different poems as *The Shield of Achilles* and *Alsono to Ferdinand*. *Let History be my Judge* is an early example of his political verse. Russia's forced collectivisation policy is the event which roused the feeling expressed here, but it is not directly referred to so that, if it were not for the date, the reader would not necessarily associate the poem with that particular policy, but with the

harsh repression of any uprising or with the invasion of a weak country: the tragedy of the imposition of impersonal policy on the ignorant and defenceless is suggested and the callous self-justification of the powerful, ironically revealed. A later poem, *The Unknown Citizen*, satirises the omnipresence of the bureaucratic state and possibly the twentieth-century obsession with statistics. It begins with particular people, as in the dramatic monologues and some of the elegies, or poems for Auden's friends. In his less successful poems he tends to be either too clever (like Gratiano's in *The Merchant of Venice*, his reasons are like " two grains of wheat hid in two bushels of chaff ") or too anxious for effect. In the same way his dry humour and use of anti-climax is very effective at times, but sometimes the very ease with which he seems to do it betrays him and the joke becomes irritating.

Apart from anthologies, in some of which he is fairly well represented, the Penguin edition, which is the poet's own selection of verse, makes a good introduction to his work. There are two collected editions, *Collected Shorter Poems, 1927–1957* and *Collected Longer Poems* (both Faber). Otherwise his large production of verse is to be found in about ten small editions (all Faber). A recording of the poet's reading of his own poems has been made by Caedmon and is well worth listening to.

Stephen Spender (b. 1909).

Collected Poems 1928–1953; *The Generous Days*, 1971 (Faber).

Spender's first poems, up to 1933, are mainly concerned with or derived from the ideas of Marxism and Freud. There are stormy calls

" Oh, comrades, let not those who follow after
—The beautiful generation that will spring from our sides
Let them not wonder after the failure of banks
The failure of cathedrals, the declared insanity of our rulers,
We lacked the Spring-like resource of the tiger— "

but what the comrades are to do is not clear. One does not expect a political manifesto in a poem, but the vagueness of the sentiment of " equal like the shine from the snow " is irritating. It is difficult to take the optimism of such a poem as *The Funeral* seriously, yet if it is meant to be ironic the wit needs clarifying. Spender's early impact and placing in literature doubtless derived from his political and psychological idiom, but the poems which have stood the test of time are those which are more personal, *e.g.*, *My parents kept me from children who were rough*, which strike a more convincing note.

From 1936 onwards his poems are often about war, first the Spanish Civil War and then the Second World War. He is moved by the fate of the ordinary civilian, particularly the young who became involved in battles they do not understand. The defencelessness of the young soldier is poignantly conveyed and in poems such as *Ultima Ratio Regum* he links the greed of society, particularly the middle classes, with the slaughter of the innocent.

The belief in socialism and the brotherhood of man, rather glibly expressed in the earlier poems, is still present, but the tone of poems from this later period is compassionate. Spender rejects the easy, outright condemnation of either war or the enemy and refuses to glorify war by celebrating heroism. In fact there are no easy answers to the questions proposed in these exploratory poems. In the introduction to his collected volume Spender speaks of them as being " malleable " and possibly this unfinished sense is both their weakness and strength.

After a gap of over twenty years, Spender published *The Generous Days*. This slim collection of lyrics is preoccupied with the brevity of life, the inevitable approach of death and with the vital power of memory to elude the passage of time. Most of the poems are autobiographical and conventional in form. Their overall tone is one of plangent nostalgia, a note struck in the opening ballad (*see* **M63**), *If It Were Not*, whose theme is the way death clarifies and enhances our vision of life. Two of the subsequent poems are notably different from the rest. In *One More New Botched Beginning*, Spender recalls vivid incidents of the past—a walk with a friend; watching his little son gazing at some hens, " absorbed in their wire netted world " and finally an Oxford scene of himself and the poets Louis MacNeice and Bernard Spencer showing each other their verses. These friends are dead and the poet's son now a grown man who has forgotten watching the hens, yet the scenes still live in the memory as a vital part of the poet's present life. Spender's realisation of this common experience has freshness and charm. The " new beginning " comes in the book's final poem, *Art Student*. Here the subject is the contemporary artist's rejection of art in favour of primitive sensationalism: " all we can do now " is " send people back/To the real thing—the stinking corpse." In his oblique, ironic assertion of the validity of aesthetic values Spender's book flares into life. He himself feels this poem marks a new start in his work, a movement away from short, predominantly autobiographical lyrics towards the possibility of longer poems and more general themes.

C. Day Lewis (1904–72).

Collected Poems 1954 (Cape) and various short, later volumes.

Of this group of poets, C. Day Lewis is probably the most prolific. He began to publish in 1925 and was associated with Auden and Spender up to the outbreak of the Second World War. His early poems show Auden's influence—the use of colloquialism, the experiment with verse form and the concern with politics. How alien this type of verse was from his own vein may be seen from the symphonic poem *A Time to Dance*, 1935, where, in one section, he parodies the Apocalypse to describe the division of society into the exploiters and the exploited:

" I saw . . .
The director placing explosives under the infant's cradle, the editor keeping a nursery for snakes:
The scientist madly driving against traffic lights, the artist studying his acne in a pocket mirror: "

Later he imitates the rhythm of popular songs.

As his expectation of a Marxist solution faded and involvement in politics lessened, due at least in part to the Spanish Civil War and then the World War, he developed a quieter tone and used the more traditional verse forms. His work is generally polished, if not particularly vigorous. His translation of Virgil's *Aeneid* in 1952 was generally well received and in addition he has written several books of criticism, as well as detective stories under the pseudonym Nicholas Blake.

Louis MacNeice (1907–63).

The Collected Poems of Louis MacNeice, edited E. R. Dodds, 1967 (Faber).

Louis MacNeice was born in the same year as Auden, published his first book of poems in 1929, and continued writing fairly steadily until 1963. He was actively interested in politics of an idealist, left-wing type and was influenced by the contemporary interest in psychology. In 1937 he joined with Auden in publishing *Letters from Iceland*, but after Auden's departure for America in 1939 the partnership, if so it may be called, dissipated itself. MacNeice continued his work as a lecturer in classics and also wrote several radio scripts for the B.B.C., including the verse drama, *The Dark Tower*.

His longest non-dramatic poem is *Autumn Journal*, which covers events from August to December 1938. Apart from its obvious historical interest—he clearly records his impressions of and fears about the political events of that period —it is an unusually convincing poem. It has

an authenticity as of Pepys's diary, but it is pervaded by a philosophical tone which brings details into focus. The verse flows smoothly most of the time, but the metre is not intrusive; in fact as an example of the "art to hide art" it is of its kind hardly bettered.

Observation of significant detail, personal reflection on the political situation as it affects society as a whole, reminiscence and a private transitory reaction are skilfully interwoven. For instance, he has spent most of the night anxiously assessing the possibilities of war breaking out and at six o'clock hears various sounds of people going to work—

"And I notice feathers sprouting from the rotten
Silk of my black
Double eiderdown which was a wedding
Present eight years back.
And the linen which I lie on came from Ireland
In the easy days
. . . . . .
. . . and I wonder what the morning
Papers will say,
And decide to go quickly to sleep for the morning
already
Is with us, the day is to-day."

Humour, often directed at himself, gives his poetry a sharpness which it might otherwise lack since he seldom seems driven by an overpowering inspiration. His use of colloquialisms and cliché is less frequent than Auden's and, possibly because of this, more effective. The opening to his tribute to his friend in *The Casualty* is a good example of this, and the rest of the poem illustrates MacNeice's gift for characterisation, for expressing admiration and regret without sentimentality.

In spite of disappointments and disillusionments MacNeice remained liberal in outlook, and sympathetic to many views (see, for example, *Bottleneck* and *The Conscript*). He may not be a major poet but he has integrity and a respect of poetry, reflected in his skilful handling of metre, which makes him an honest poet rather than a brilliant dilettante.

4. Dylan Thomas (1914–53).

Collected Poems, 1952 (Dent).

In many ways his poetry could hardly be more different from that of the previous group. Dylan Thomas, as a poet at least, was hardly touched by social concerns, and was uncommitted politically. His poems do not exhibit the intellectual force which Auden and Eliot's do. If these last-mentioned poets derived their inspiration from metaphysical poets like Donne, then Dylan Thomas may be said to derive his from poets such as Southwell or the visionary Blake.

The theme of much of his poetry is the oneness of all creation, the unity of experience: the human is intermingled with the divine, flesh and spirit are indivisible, and the world we inhabit is not essentially different from us,

"The force that through the green fuse drives
the flower
Drives my green age; that blasts the roots of
trees
Is my destroyer."

Death is incipient in birth and so in love—

"The word flowed up, translating to the heart
First characters of birth and death."

Sometimes death is accepted as in *And death shall have no dominion* and in *A Refusal to Mourn*; at other times Thomas seeks to defy death by protest:

"Do not go gentle into that good night
Old age should burn and rave at close of day."

The condensed language, particularly the use of verbal nouns and adjectives, reflects, sometimes not very clearly, this sense of the unity of creation.

His use of language though much imitated, remains recognisably his own. He uses cosmic symbols: sun, heaven, stars, sea, fire, and wind; images such as womb, bird, blood, and tomb; colours: green, gold, red, blue, and black. Much of the verse—that is when it is not overloaded with images—evokes kaleidoscopic pictures and the rhythmic metrical pattern is generally strong, which is possibly why he was in his own lifetime a popular poet. He draws too a great deal on biblical symbols and this coupled with the use of formal sound patterns, assonance, rhyme, and alliteration gives his verse an incantatory sound which is quite impressive. Finally he has resuscitated the "transferred epithet technique."

At his best he has produced moving but unsentimental celebrations of childhood, *Fern Hill*, *Poem in October*, *Over Sir John Hill*; some religious poems, for example, the unusual pattern poem *Vision and Prayer* and some "occasional" poems.

Very good recordings of Thomas's readings of his poems have been made by the Caedmon group.

5. The "Movement" Poets.

Robert Conquest's anthology *New Lines*, 1956 (Macmillan), marks the next stage—sometimes called the "Movement"—in English poetry. In his introduction Conquest remarks that groups of poets typical of their decade were "presented to public fire by anthologies which took up definite positions." His anthology was prepared in the belief that "a genuine and healthy poetry of the new period has established itself." The main objections he makes to criticism published from the beginning of the Second World War is that it encouraged poets "to produce diffuse and sentimental verbiage or hollow technical pirouettes." The poets he chose, apart from being contemporary, have in common only the acceptance that "poetry is written by and for the whole man, intellect, emotions, senses and all," and on the technical side a "refusal to abandon rational structure and comprehensible language." However, in their reaction against the undisciplined expression of emotion, the Movement poets tend to go to the opposite extreme. Their writing is highly intelligent and often witty, but generally seems more cerebral than truly imaginative, lacking the inspiration of passionate feeling. The wry self-mockery and hopelessness of much of Larkin's verse is typical of the work of the Movement as a whole, but some younger poets, notably Gunn and Hughes, who were early associated with the group, have gone on in another, more vigorous direction.

Philip Larkin (b. 1922).

The North Ship, 1945; *The Less Deceived*, 1955; *The Whitsun Weddings*, 1964 (all Faber).

Like Dylan Thomas, Larkin recalls his childhood, but he refuses to romanticise it. In *I Remember, I Remember*, he speaks of Coventry where he was born as a place where his childhood was "unspent" and he lists the crises commonly associated with precocious youth which did not occur. So far the poem is mildly ironic, but its end is disturbing:

"'You look as if you wished the place in Hell,'
My friend said, 'judging from your face.' 'Oh
well,
I suppose it's not the place's fault,' I said.
'Nothing, like something, happens anywhere.'"

The sense of emptiness, of opportunities untaken, of flatness, is a theme of much of Larkin's verse, *e.g.*, *Work*, *Departures*, *Triple Time*, but the self-mockery and irony give the work a pointedness which most elegaic verse lacks; when he reflects on the past he is neither nostalgic nor resentful. A conversational tone is used to attract attention, but the language is a "*selection* of the language really used by men"; he does not indulge in the vague slipshod phrasing of what passes for the conversation of "ordinary people." A good example of his style is *Church Going*, a reflection on the future of churches when they "fall completely out of use," which raises the whole question of belief (in values neither immediate nor material).

Thom Gunn (b. 1929).

Fighting Terms, 1954; *The Sense of Movement*, 1957; *My Sad Captains*, 1961; *Touch*, 1967; *Moly*, 1971 (Faber).

At first glance Gunn's poetry seems as contemporary as the morning paper. Titles such as *On the Move*, subtitled *Man you gotta Go*, *Black Jackets*, *Elvis Presley*, suggest, rightly, that his poetry is rooted in the present, but not in such a way that it will be incomprehensible when the present has become the past. He is concerned with violence in the classical world in *The Wound* and *Helen's Rape*, in the sixteenth century in *A Mirror for Poets*, and in the twentieth century in *Claus von Stauffenberg*, in personal relationships as well as public, but it is not an unthinking surrender to mere excitement or admiration of brutality, but a recognition of its necessity:

> " In this society the boundaries met
> Of living, danger, death, leaving no space
> Between, . . .
> . . . Yet at this point they found
> Arcadia, a fruitful permanent land."
> (*A Mirror for Poets*).

In *Saint Martin and the Beggar*, Martin, the saint of man, must learn to fight before he can " grow " and then without hesitating he halves his cloak to cover the beggar. He is justified because his action was natural. The tragedy of modern man lies in his inability to marry instinct, intention, and action:

> " One joins the movement in a valueless world,
> . . . . . .
> At worst, one is in motion; and at best,
> Reaching no absolute, in which to rest,
> One is always nearer by not keeping still."
> (*On the Move*).

Ted Hughes (b. 1930).

The Hawk in the Rain, 1957; *Lupercal*, 1960; *Wodwo*, 1967; *Crow*, 1970 (Faber). There is also a small book of *Selections* from Hughes and Gunn (Faber).

There is some similarity between the early poetry of Hughes and Gunn. Both worked in America; both developed a concise style to mirror the toughness of their attitude to experience, their refusal to make the rough places smooth.

This said, the differences become more apparent as their individuality becomes clearer. Hughes uses animals, in whom the primitive instinctual drives are more evident than in man, to symbolise human dilemmas, but his animals are far from being ciphers. In *Pike*, for instance, the pike exists in its own right and, since Hughes did collect animals in his boyhood, the incident

" Suddenly there were two. Finally one

With a sag belly and the grin it was born with "

is probably true. But the recollected " nightmare " at the end of the poem goes beyond a boy's terror. The pond he fished, the eye, the dream darkness are symbolic both of the violence which lay in his own subconscious and that of the human race. The human being too is potentially a killer from the egg.

In other poems Hughes is searching for an identity. In *An Otter*, the otter

> " Gallops along land he no longer belongs to;
> Re-enters the water by melting."

At one level we have the hunt which loses and then finally catches the otter, but at another level there is the self, " attendant and withdrawn," the individual who " does not take root ".

In *Wodwo* Hughes moves away from naturalistic animal imagery. His Ghost Crabs are the creatures of a nightmare and in *Crow* the protagonist is a mythical figure, the pitiful but Satanic embodiment of the poet's increasingly grim vision.

In *Poetry In The Making*, originally a series of school broadcasts, Hughes gives fascinating accounts of his methods of composition and of the geneses of some of his early poems.

6. English Poetry in the 1960s.

Now the vogue for the " Liverpool sound " in pop music became a vogue for the " Liverpool sound " in pop verse. The voice of the Barrow Poet, and many another itinerant bard, was raised in the pubs and cellars of the metropolis and the day of the Poetry and Jazz Festival came upon us in the time of the Children of Albion (see the Penguin anthology of the same name, subtitled *Poetry of the Underground in Britain*, 1969).

Day Lewis became Poet Laureate and Graves, Blunden and Fuller followed Auden as the Oxford Professor of Poetry, but more people listened to reviewer and critic Alvarez as he proclaimed the eclipse of Larkin and the " genteel " Movement (*q.v.*) and extolled the greatness of the American Confessional school (*q.v.*). However, when *The Review*, a leading poetry quarterly, recently asked some thirty-five American and British poets critics and editors what they had found encouraging about the poetry of the last decade, the name most often referred to was Larkin's *Whitsun Weddings* and while the speakers clearly admired the work of Lowell and Plath they seemed equally impressed by that of two relatively unknown British poets, Geoffrey Hill and Peter Porter.

Geoffrey Hill (b. 1932).

For the Unfallen, 1959; *King Log*, 1968; *Mercian Hymns*, 1971. (André Deutsch).

Our understanding and appreciation of Hill's strikingly original poetry depends to some extent upon a knowledge of the Bible, of Classical and Celtic myth and of mediaeval history, but more upon a relish for the ironic ambiguities of words and a delight in sensuous imagery and verbal music, for, like Yeats and Eliot's, Hill's poetry captures our attention with its vivid word play and musical power. At first we may feel that we can glimpse only a shadow of the significance of poems like his *Funeral Hymns*, but gradually, as their images sink into our subconscious minds, their import becomes clearer, though often still tantilisingly ambiguous and elusive.

Hill's first book, *For the Unfallen* is now out of print, but most of its poems can be found either in *Penguin Modern Poets 8* or in *The New Poetry*, a Penguin anthology edited by A. Alvarez.

Even in this early work Hill's mastery of form and language strikes one immediately. He adapts and develops traditional metres, verse forms and rhyme schemes into new pattern and renews outworn metaphors, as if by a sleight of hand, sometimes altering their form, as when he writes of " the mouthy cave ", at others placing them in a context where their meaning becomes reverberatingly ambiguous, as in *The Guardians*. Here he speaks of the young who have been caught in a thunderstorm while sailing. The old watch and then " Quietly they wade the disturbed shore:/Gather the dead as the first dead scrape home."

As these brief examples also show, Hill has a vivid command of pictorial detail and verbal irony. His approach is usually oblique, as in the later poem, *September Song*, an elegy subtitled *born 19.6.32—deported 24.9.42*. It begins,

> "Undesirable you may have been, untouchable
> you were not. Not forgotten
> or passed over at the proper time."

Hill's measured tone is so deceptively calm, his imagery so condensed that the full impact of his words is delayed, and thereby intensified as gradually we become aware of the multiple significance of " undesirable ", " untouchable ", " Not forgotten ", " passed over ", " proper time ", of the menace conveyed in the transition from the conditional to the indicative voice, of the clinching effect of the antithesis, enhanced by the run-on line and the counterpointed pattern of major and minor stresses, suddenly broken by the abrupt caesura following " not ".

Here, as elsewhere, Hill's work is profoundly disquieting in its effect. He writes of innocence and corruption, violence and sacrifice, suffering and abnegation of responsibility, suggesting that in these matters man is as he always has been, that past and present are one. Within the general moral concern in each book we may distinguish a particular underlying theme: In *For the*

Unfallen it is "moral virtue", in *King Log*, "matters of power and commandment."

The opening poems of *King Log* explore this theme in terms of the Classical age, of mediaeval Catholicism, sixteenth-century humanism, nineteenth-century Calvinism, twentieth-century Nazism and existentialism. The sense of the indivisibility of past and present which permeates the poems is most obvious in the opening *Ovid in the Third Reich*, more obliquely expressed in the splendid *Funeral Hymns*, a set of eight unrhymed sonnets inspired by the Wars of the Roses.

The second part of *King Log* places Hill's theme in a new perspective through a series of moving poems of rejected love, *The Songbook of Sebastian Arrurruz*. Arrurruz is an imaginary Spanish poet, his name intended to recall both St. Sebastian—martyred with arrows—and the word arrow-root, suggesting that the arrows of love which pierce the poet are centred in his own person. Arrurruz's songs are addressed to the wife who has deserted him, but even while yearning for her he acknowledges her freedom and independence.

The underlying theme of Hill's third book, *Mercian Hymns* unites the concern of the earlier volumes in an exploration of private and public morality. In this modern "epic" the myth-making quality already apparent in *Funeral Hymns* and *The Songbook*, becomes more noticeable. Hill's hero is Offa, an eighth-century king of Mercia, here conceived of as the "presiding genius of the West Midlands, his dominion enduring" to the present day. Elements from primitive legend are used to suggest an even longer timespan by associating Offa with the British fertility god, the horned Cernunnos. The thirty stanzas of the poem, rich in pictorial detail and subtle irony and humour, cover such varied topics as childhood, money, laws, industry, war and death. Not the least remarkable aspect of this extraordinary poem is Hill's achievement in having created a completely new stanza form, inspired by the canticles of the early Christian church.

Peter Porter (b. 1929).

Once Bitten, Twice Bitten, 1961; *Poems Ancient and Modern*, 1964; *A Porter Folio*, 1969. (Scorpion Press); *The Last of England*, 1970; *Preaching to the Converted*, 1972; *After Martial*, 1972. (Oxford University Press).

An Australian, Porter came to England in 1951 for "the opportunites which a common language gives to seek a wider frame of reference." He began as a satirist, but feels he is now moving towards a different position, an opinion supported by the increasingly complex and individual elegiac tone of recent poems.

In *The Sadness of the Creatures* Porter speaks of himself as "an historical cat", saying, "I run on rails". Both the forms and themes of his poems reveal his concern with "the continuity of the living and the dead . . . the only reality I can find in England". He has experimented with free verse but also uses and skilfully adapts traditional metres and verse forms.

Initially he may seem, as Eliot said of Webster, to be "much possessed by death", but he is not pessimistic and "death" has a multiple significance for him. In *Who Gets the Pope's Nose* Porter speaks of death as "God's greatest miracle" because it brings relief from suffering; in *Fossil Gathering* it is the means by which our essential nature is revealed: ". . . every feeling thing ascends from slime/to selfhood and in dying finds a face." In *There Are Too Many of Us* Porter equates death with the oblivion which should quickly descend upon the trivia of life. He suggests that it is a necessary condition of progress and that if we arrogantly complain at its inevitability oblivion comes all the sooner, for writers as for other men:

> ". . . we world eaters
> Are eaten in our turn and if we shout
> At the gods they send us the god of death
> Who is immortal and who cannot read."

Evolution presents the related concept of death as the process which enables life to renew itself, and Porter here draws a vivid parallel between Resurrection, symbolised by the resurrection of the Jewish nation in the state of Israel, and evolution, symbolised by the continuous renewal of the body's tissues. In *Preaching to the Converted* the "converted" are imaged as dead, incapable of change, fixed for ever in the marble postures of memorials in the church of San Lorenzo, they have only "a *Grundrisse*" of the possibilities of life. (*Grundrisse:* a set of sketches, rough drafts; an outline syllabus; also, the title of a work by Marx).

Porter's writing is often extremely witty and he has produced some very amusing and ingenious light verse, such as *Mort aux chats*. His work can present unusual initial difficulties because its imagery is often allusive rather than sensuous, fragmentary rather than sustained and many poems combine esoteric references with a casual throwaway style, lacking verbal music, but in recent poems such as *May 1945*, *Fossil Gathering*, and the more personal *At Whitchurch Canonicorum* the imagery is sustained and the tone has a lyrical intensity.

Notes to a Biographer, *Homily in the English Reading Room*, *John Marston Advises Anger* and the more esoteric *Widow's Story* resemble Auden in the ways they show past jostling present and juxtapose learned references to music, literature and painting with references to the ephemerae of modern life. Porter also resembles Auden in the way he uses industrial and urban imagery. His other master is Pope, but in his satiric writing he generally eschews the felicitous elegance and visual immediacy of Pope's verse and his satiric juxtapositions and antitheses therefore often lack the force which Pope's command. However, in his better satiric verse, Porter applies stylistic devices learned from Auden to the subject matter of Pope and the result is powerful and individual. *The Workers* presents the young lovers Valerie and Hugues, "a torturer's and a peasant's descendants / On the broad back of money". Porter wittily describes Valerie's eye make-up in terms of industrial processes and building maintenance:

> "It takes a whole Black Country
> and at least one new oxidizing process
> to maintain the canals in her fallen eyelids".

The fragmented style of much of his satiric writing seems to derive from an attempt to express the distorted values and incoherence of a life in which death has become the "great unmentionable" and "novel" is so often spoken of as if it were synonymous with "valuable". Porter mocks the pretentions and ephemeral fashions of contemporary pundits and versifiers and in *There Are Too Many of Us*, alluding to the "great theologian" (possibly the seventeenth-century priest and poet John Donne, *see* his *Satyre III*) Porter suggests that no-one has the sole key to wisdom and that the valuable thing in life is not anything new but man's continuing search for truth, which involves

> ". . . a tradition
> Of mind going uphill and always
> Getting steeper."

He contrasts the "lucky genius", who "refines his burden to one thing at a time" with "his passenger friends" who "are quacking in the beautiful incomprehensible languages" and ridiculously try to preserve everything on video tape—"nothing is allowed to die."

In *Elegy* he draws ironic contrasts between the advances of bureaucracy and the steady rhythms of the natural world, the discoveries of science and continuous indignity and suffering:

> ". . . the trees perform their ritual
> leaf-shedding in the month of the setting-up
> of a Ministry of Technology. A world of lasers
> has millions who must be blanket bathed,
> and a species of rat-like marsupial
> is officially declared extinct—
> the Ars Nova sound is a special
> test of high-fidelity equipment."

Porter has spoken of the indelible impression of suffering he bears as a result of childhood experiences of the Depression in Brisbane and the loss of his mother, who died when he was nine. His awareness of the pain of mankind and of our inhumanity towards other people and creatures finds most powerful expression in works such as *The Sins of the Fathers, Story from Time of Disturbance.* However, some of Porter's finest writing is to be found in a handful of recent lyrical and elegiac poems. Here his gift for creating vivid precise images is used more freely and extensively and while many of his earlier poems had weak endings, as if he were afraid of being thought sententious, he now has the confidence to end boldly, as in *Thomas Hardy at Westbourne Park Villas:*

" Here, rather than in death-filled Dorset,
I see him.
The watchful conspirator against the gods
Come to the capital of light on his own grim
Journey into darkness; the dazzle would tell
Him these were the worst of possible odds—
ordinary gestures of time working on faces
the watermark of hell. "

Porter has said that his aim is now to " go back deeper into English poetry . . . and at the same time to put out feelers towards the European imagination "—a process already begun in his recent collections *The Last of England* and *Preaching to the Converted.* His latest book, *After Martial,* is a fine set of verses based on Martial's epigrams.

7. A Note on Twentieth-Century American Poetry.

The American Pound and the Anglo-American Eliot were cosmopolitan writers, as much, if not more at home in Europe as in America. Their poetry may, sometimes does, refer to specific scenes and places, but in general *Hugh Selwyn Mauberly, The Pisan Cantos, The Waste Land* and *Four Quartets* express a vision of twentieth-century man seen by poets highly cultivated and steeped in the history of civilisation.

By contrast, most American poets of our time, though often equally learned, have been self-consciously American, deliberately concentrating their attention on the immediate national, or even provincial, setting in which they find themselves.

One reason for this emphasis stems from the ideas of the Imagists, including Pound, who said that the writer should strive to create poems composed of vivid, concentrated and highly evocative images. Americans like William Carlos Williams (1883–1963) felt that one could best do this by focusing one's attention on the immediate environment.

At the same time they were eager to find ways of expressing the specifically American experience of life, which had hitherto found few outlets in poetry. This was especially important to Williams, who felt that the American spirit was being stifled by the dead weight of English literary forms. He said, " everything we do is tied up with words ", but, although many Americans " no longer speak English ", when writing they still used the for them stultifying syntax and " the prose or poetical rhythms which bind us to our pet indolences and mediaevalisms." American poets, he said, must break through the " deadness of copied forms which keep shouting above everything that wants to get said today, drowning out one man with the accumulated weight of a thousand voices of the past."

For Williams the writer to whom to turn for inspiration was the nineteenth-century Whitman. His derided free verse (*see* M61 suggested the possibility of new literary forms, within which the Imagist techniques could be deployed.

Two of the other pioneers of twentieth-century American poetry were more influenced by the Symbolists' emphasis on the music of poetry (*see* M44 than they were by Whitman. In her search for a freer and more musical verse form Marianne Moore (b. 1887) developed syllabic metre (*see* M58), while Wallace Stevens (1879–1955), one of the greatest poets of our century, used Symbolist techniques to bring new and sparkling life to traditional verse forms. In an age when most writers spurned the iambic pentameter and blank verse as museum pieces Stevens shows them still vigorously adaptable and tuneful.

None of these writers saw the development of new techniques as an end in itself, but as the necessary means for expressing a new vision of life. They shared a high concept of the poet's role which many English writers would now regard as misguided. Auden said that nothing he had written had saved anyone from the concentration camps or gas chambers. These American writers of a slightly older generation felt more optimistic. They shared a radical humanism which led them to rejoice in life's beauty and man's creative power as well as to recognise the cruelty of the world. They saw poetry as replacing religion and offering a new, illuminating vision of life in all its joy and sorrow.

Stevens said that poetry must be " abstract "—that is abstracted, separated from the old visions of life, including those offered by religion—it must present new and original insights. It must also give pleasure, not by encouraging the reader to indulge in fantasies but by offering him truthful images of reality in beautiful and illuminating forms. Poetry must also change, that is give the reader new insights into life, not confirm him in his old ones. These are the recurrent themes of Steven's poetry and find their most complete expression in his great work *Notes Toward a Supreme Fiction.*

Stevens's attitude to poetry was shared by Moore and Williams, but Williams was a less speculative, more prophetic writer. He sought not only to offer a clear vision, but to arouse man's hatred for the brutal, life-denying materialism of industrial America, exemplified in the suburb of Paterson, where he worked as a medical practitioner. This radical strain has been taken up by many later American writers inspired by Williams's poem *Paterson.*

Anyone interested in the development of twentieth-century poetry should read the work of Pound, Williams, Moore and Stevens. They are all highly enjoyable as well as influential writers. Paperback editions of their poems are easily available and selections from their theoretical prose can be found in J. Scully's *Modern Poets on Modern Poetry.*

8. The Beat Poets.

The name " Beat Generation " (*see* J7) was applied to a group who were radical critics of American life under the complacent Eisenhower administration, which seemed to them to ignore the ugliness and cruelty of life in the industrial areas' " concrete jungles ". The distinctive protest of the Beats involved a rejection of all middle-class ideas of respectability. They practised communal living, often in considerable poverty, and had a relaxed attitude towards employment, sex and drugs. They were generally anarchic pacifists, but uninterested in politics as such.

Their attitudes find formal expression in Kerouac's novel *On the Road,* 1951, Burroughs's *Junkie,* 1953 and *The Naked Lunch,* 1959, and in the poetry of, among others, Laurence Ferlinghetti (b. 1923), Gregory Corso (b. 1930) and Allen Ginsberg (*q.v.*). A selection of their poems can be found in *Penguin Modern Poets 5.*

The journalist John Clellan Holmes defined the word " Beat " as " involving a sort of nakedness of soul, a feeling of being reduced to the bedrock of consciousness." Such " nakedness " is a distinguishing mark of Beat verse, which may be thought of as an extreme form of confessional poetry (*q.v.*). Its principles, in so far as they have been formulated by the leading Beat poet Ginsberg, take the Symbolist preoccupation with the expression of the unique, individual consciousness to its logical, egocentric conclusion. On the other hand believing, that art falsifies the truth of experience, the Beats in principle reject that fastidious care with which the Symbolist sought to

formulate their experience. For the Beats, the beauty of a poem's form is not the result of artistry or talent, but is determined by the writer's character: a good, honest man will produce a good, honest poem, a rascal will compose bad verse! However, like most poets, in practice, the Beats sometimes break their own rules. The best of their work is far from artless, though its forms are often as unusual as its content is unconventional.

Allen Ginsberg (b. 1926).

Howl and Other Poems, 1956; *Kaddish and Other Poems*, 1961; *Reality Sandwiches*, 1963; *Planet News*, 1968; *Ankor Watt*, 1968; *The Fall of America, poems of these states* 1965–71, 1972. City Lights Books.

Ginsberg was brought up in Paterson, New Jersey, where his family was known to W. C. Williams and Williams, whose work Ginsberg is said to admire, wrote a warm introduction to the younger poet's first book, *Howl and Other Poems*. Like Williams, Ginsberg is a writer in the prophetic tradition of Whitman, Shelley and Blake. He was also early impressed by the writing of the eighteenth-century visionary Christopher Smart, but it was to Whitman in particular that he was indebted for the free verse techniques (*see* M61) which he used for many of his most impressive early poems.

It is important we should bear in mind that most of Ginsberg's work is intended to be read aloud—performed or chanted—to a sizeable audience, not quietly brooded over in solitude, although the power of such poems as "Kaddish" is clear even to the silent reader. Ginsberg himself has a charismatic personality, a theatrical flair, shrewd intelligence and a lively and amiable sense of humour, all of which add to the captivating power of his performances.

His finest work is contained in the two early collections, *Howl* and *Kaddish*. The famous—or notorious—"Howl" is a vatic lament for the way Ginsberg's talented contemporaries have, he feels, been destroyed by the inhumanity of American life. It is written in long, free verse canticles, the first sixteen pages comprising a single sentence, listing the ways in which "the best minds of my generation" have been driven to suicidal despair. It expresses a horrifying, if at times hysterical, vision of urban America.

"Sunflower Sutra" in the same volume, is a more concentrated and powerful piece of writing, in which a skeletal grey sunflower, growing in a filthy railway siding by a San Fransicso dock, becomes a symbol of man's courageous will to survive even in the harshest surroundings. The poem vividly exemplifies Ginsberg's talent for creating precise and original pictorial images, such as that of the sunflower itself, with its

"corolla of bleary spikes pushed down and broken like a battered
crown . . .
. . . sunrays obliterated on its hairy head
like a dried wire spiderweb . . ."

"America", another poem in Ginsberg's first collection, is more self-absorbed but concludes with a flash of characteristic humour as the poet speaks of a "Reds-under-the-bed" scare:

"The Russia wants to eat us alive. The Russia's power mad. She
wants to take our cars from out our garages.
. . . Her make us all work sixteen hours
a day. Help.
America this is quite serious.
America this is the impression I get from looking in the television
set.
America is this correct?
I'd better get right down to the job.
It's true I don't want to join the Army or turn lathes in precision
parts factories, I'm nearsighted and
psychopathic anyway.
America I'm putting my queer shoulder to the
wheel."

In his later work, such as a poem addressed to the singer Bob Dylan, Ginsberg sometimes verges on the sentimental, but his earlier "Kaddish", a lament for his unhappy mother, and "Aunt Rose", are at once tender and objective poems, creating memorable images of these two elderly women.

In 1965, Ginsberg, who had earlier known a transcendental experience of identity with "Supreme Reality" realised that he must stop living on the memory of past visions, "which is not the actual awareness of *now*." His later work therefore takes the form of diffuse verse "diaries", "chronicle tape recorded scribed by hand or sung condensed, the flux of car train air plane dream consciousness . . ." These verses lack the power of his early poems, although they contain still vivid images and flashes of humour.

9. The Black Mountain Group.

The most important poets generally referred to under this title are Charles Olson (*q.v.*), Robert Duncan (b. 1919) and Robert Creeley (b. 1926). Associated names include those of Denise Levertov (b. 1923), Ed Dorn (b. 1929) and Gary Snyder (b. 1930).

All these poets taught or studied at Black Mountain College in North Carolina, an experimental adult education centre founded during the Depression. Until its closure in 1956 it was the focal point for many who were discontented with accepted academic ideas and methods. It attracted a galaxy of talent, including the philosopher Dewey, the artist De Kooning and the musician John Cage.

Charles Olson (b. 1910).

Projective Verse, 1950 (in J. Scully, ed., *Modern Poets on Modern Poetry*, Fontana Bks., 1966); *The Maximus Poems*, 1960, *Maximus IV, V, VI*, 1968, both Cape Goliard Press.

Olson is the most influential of the poets associated with Black Mountain College. He has published a number of verse collections, including *In Cold Hell, in Thicket*, 1953, and *The Distances*, 1961, but his most important works are the two volumes of Maximus poems and the essay *Projective Verse*.

In this essay, Olson sought to define his concept of a poem. He speaks of it in terms of physics as a "high energy construct", imagining the poet's experience as a generator which charges the battery, or poem, whose energy is then projected to another person when he plugs into it by reading or listening to the poem.

In order to construct an efficient poetic battery the writer must think of his work in terms of its energy field. Its form should be determined solely by its content. However, Olson also says, somewhat paradoxically, that the writer must consider how "to shape the energies so that the form is accomplished" and suggests that the solution to this problem can be found in the dictum "in any given poem, always one perception must MOVE, INSTANTER, ON ANOTHER!"

The writer should avoid similes and descriptive passages, which dissipate a poem's energy, and, in so far as formal considerations enter his mind, he should concentrate not on rhyme or metre, sense or sound, so much as on the syllables, which are the "figures of the dance" and the line which is its "threshing floor" (*see also* M58). The line's length is determined by the poet's sense of breathing. Pauses are indicated not only by line endings, where they should be as long as "it takes the eye . . . to pick up the next line", they are also suggested by spacing: "space as long as the phrase before it . . . means that space to be held, by the breath, an equal length of time." Very light pauses are indicated by a diagonal line / rather than a comma, which has undesirable grammatical connotations. Varying amounts of indentation suggest the proper juxtaposition of the images.

Olson wrote his essay in the year that he composed the first of his Maximus poems and his ideas are helpful in understanding how these should be read, for, as the reader will quickly discern, they are best read aloud.

At his finest, as in the opening and closing poems of the sequence, Olson is a writer of considerable lyric power but in some poems, particularly those like " Later Tyrian Business " in the second volume, an elaborate and self-conscious typography confuses the reader and detracts from the poems' significance.

The subject of the Maximus sequence is the city of Gloucester, Massachusetts, and the treatment is heavily influenced by W. C. Williams's *Paterson*. The predominant theme, as in Williams's poem, is the way the region's inhabitants and its natural resources have from the time of the first settlers been corrupted and destroyed by capitalism and " pejorocracy ". By " pejorocracy ", a term coined by Pound, we are to understand a materialistic form of power based on the denial of life's essential meaning and purpose.

As in *Paterson*, passages of verse are divided by extracts from prose documents, letters and account books, etc., but the matter is generally less varied and less well chosen than that in Williams's poem. It depends heavily upon lists of long-dead settlers' names, precise accounts of their ownership of land, the relative positions and sizes of their fields, and so on. Such a plethora of antiquarian detail might possibly be meaningful to one thoroughly versed in the documents themselves and in the local history and geography of Gloucester, but a much more rigorous selection would have concentrated the poems' energies and enhanced their significance. As it is, the work as a whole seems prolix, and self-indulgent, although it also contains powerful and beautiful passages which it would be a great pity to miss.

10. The " Confessional " Poets.

The term " confessional poetry " seems to have been used first by reviewers of Lowell's *Life Studies*, poems which arose from their author's suffering a mental breakdown. It has since been applied to the work of Sylvia Plath and Anne Sexton, which also derives from the immediate experience of mental illness and, like *Life Studies*, expresses feelings of guilt, bitterness and isolation, the material of the confessional or the psychoanalyst's couch.

The label " confessional " is also used in a more general, though allied sense, to denote work in which the poet makes an uninhibited confession of hatred, addiction, lust or similar experience, about which, usually, most of us are reticent.

In " confessional " writing the poet's need to objectify his experience, in order to give it artistic validity, presents itself in an acute form. Its resolution demands the rare courage and technical virtuosity that Eliot displayed in *The Waste Land* and Lowell approaches, in a very different way, in *Near the Ocean*.

Robert Lowell (b. 1917). *See also* **Section I.**

Poems 1938–1949, 1950; *The Mills of the Kavanaughs*, 1951; *Life Studies*, 1959; *Imitations* 1961; *For The Union Dead*, 1964; *Near the Ocean*, 1967; *Notebook*, 1970; *History*, 1973; *For Lizzie and Harriet*, 1973; *The Dolphin*, 1973. (Faber).

In an interview, published in J. Scully's *Modern Poets on Modern Poetry*, Lowell records how he was early drawn to the work of Latin, Elizabethan and Jacobean poets. His own mature writing reflects the continuing influence of these early mentors, with whom he shares an anguished sense of the fragility and transience of beauty and a revulsion from the brutal, vicious materialism of the society in which he lives.

His first important work, *The Quaker Graveyard in Nantucket*, 1945, is an elegy for a cousin drowned while serving in the navy during the Second War. The poem presents this cousin as continuing the brutal tradition of the Quaker whalers of Nantucket, and links him with Ahab, the tragic, deranged hero of Melville's *Moby Dick*. The vigour of the poem's language, the musical skill with which Lowell evokes the sounds and atmosphere of the bleak Nantucket coast and the force of his revulsion from the whalers' obscene cruelty are immediately impressive. As Hugh B. Staples has noted in his valuable reference book, *Robert Lowell—the First Twenty Years*, a central theme of the poem is " human evolution, considered as a part of God's plan." Here, as in much of his later work, Lowell shows the aggressive individualism of men bringing a return to primitive violence. The gentle, pastoral stanza VI presents the ideal, the figure of the Virgin, who, " Expressionless, expresses God." However, this stanza lacks the force of the others. The affirmation of faith in the poem's concluding line is similarly less convincing than Lowell's expression of revulsion from the Quakers' primitive lust for power and wealth.

The poem's images have multiple significance. The whale, " IS, the whited monster," is at once a symbol of Being Itself, of the vengeful Jehovah and of Iesu Saviour. It is the victim of the sailors' greed and also the agent of their death and damnation, a whited sepulchre, an image of their corrupt faith. The sea is the god Poseidon, " the earth shaker ", and also the primitive source of life and life itself, " hurt " and " fouled " by man.

These and allied images take on new significance in Lowell's later poems, where they replace the Catholic symbols of his early work, as he strives to achieve a more flexible, resonant style, which will give objective validity to his vision. In his mature work the sea and water continue to symbolise life, particularly the life of the spirit. Fish at times represent the primitive violence man has loosed upon the world, but the fish is also an image of vitality struggling against " the stone and bone-crushing waterfall." Monsters become " grunting " " yellow dinosaur steamshovels ", possessive " dragons " and the Gorgon, a fearsome, yet beautiful and pitiful, " tyrant " and " tyrannicide."

Lowell's use of such images is linked with his frequent evocations of the language and imagery of the Bible, particularly the Old Testament and the Apocalyptic books beloved of the New England Puritans. He applies such language and imagery to the life-denying creeds of the Puritans themselves and to all those who seek to dominate their fellows, driving in " stakes " to " command/the infinite " and creating " God the Logos " in their own image, a tyrant with " bloody hands ". Lowell combines such Biblical allusions with references to Classical myths—particularly that of Perseus and Medusa—to give his work wider significance and fuller perspectives. He uses American place names with religious and historical associations, Mount Sion, Concord, Carthage, and writes of contemporary life in terms of that of Ancient Israel and Rome, as in the following passage, where the insistent rhythm, the punctuation and feminine rhymes accentuate the image of the clumsy military machines irrevocably lurching toward their shattering end:

" Hammering military splendor,
top-heavy Goliath in full armor—
little redemption in the mass
liquidations of their brass,
elephant and phalanx moving
with the times and still improving,
when that kingdom hit the crash:
a thousand foreskins stacked like trash . . ."
(*Waking Early Sunday Morning*).

In his early verse Lowell imitated the metrical forms of Elizabethan and Jacobean poetry. His middle period was a time of experiment: the dramatic monologues of *The Mills of the Kavanaughs* are written in more colloquial run-on couplets similar to those of Browning; *Life Studies* and *For the Union Dead* contain a number of poems in free verse. His volume, *Near the Ocean*, marks Lowell's return to stricter metrical forms, using a stanza based on four couplets, which he now deploys with the deceptive skill of a master. His earlier experiments with style and metre and the experience he has gained by writing plays and

by recreating poems from Latin and other languages for the volume *Imitations*, now enable him to write with vigorous simplicity and haunting beauty:

> "Lost in the Near Eastern dreck,
> the tyrant and tyrannicide
> lie like the bridegroom and the bride:
> the battering ram, abandoned, prone,
> beside the apeman's phallic stone."
> (*Near the Ocean*).

Although the autobiographical poems of *Life Studies* have been among the most widely noted of Lowell's work, some later volumes seem of more lasting importance. They express a complex, tragic vision of life in a "black classic" world of "lost connections". We are all "tyrants". Mussolini was "one of us." Caligula is our "namesake" and "tyrannicide" itself a most arrogant form of tyranny, bringing widespread suffering and destruction:

> "I have seen the Gorgon.
> The erotic terror
> of her helpless, big bosomed body
> lay like slop.
> Wall-eyed, staring the despot to stone,
> her severed head swung
> like a lantern in the victor's hand."
> (*Florence*).

"Pity the monsters!" "Pity the planet, all joy gone/from this sweet volcanic cone."

Lowell's later poems express the anguish of our almost impossible quest for "asylum, peace". "We are like a lot of wild/spiders crying together/ but without tears." Innocence, goodness and beauty, life itself, are as fragile as "the orange and black/oriole's swinging nest!" In *For the Union Dead* he suggests we can survive only by having the "angry wrenlike vigilance" which chooses death rather than "savage servility" or the security of "a Mosler safe, the 'Rock of Ages'/that survived the blast." The ultimate test is whether we dare become "alive enough" to "die".

Like Yeats, Lowell has come to feel that we experience innocent joy only in the creation and contemplation of art. Exploring the frightening "corners of the woodshed", he creates from its "lumber" poems that give "darkness some control", evoking joy even while they "sing" "despair."

His four most recent collections, beginning with *Notebook*, present various stages in the composition of three sets of poems written in a fairly loose sonnet form.

The 1970, English, edition of *Notebook* differs from the first, American, one of 1969. About a hundred of the poems were modified and nearly a hundred new ones added. They were arranged according to no discernible method. Lowell said their disposition was "intuitive . . . not a pile or a sequence of related material." However, in his three subsequent volumes, the poems of the 1970 *Notebook* were further modified, in some cases drastically, and re-arranged to form three sequences.

The first, *History*, is a chronological series about people and events from Biblical and Classical times to the present day. It contains a number of new poems and also new versions of some from Lowell's earlier collections, *Near the Ocean*, *Imitations* and *Life Studies*, as well as from *Notebook*.

For Lizzie and Harriet includes a little new work but most of it is derived from *Notebook* and forms a sequence concerning Lowell's relationship with his former wife, Elizabeth, and his daughter, Harriet.

The Dolphin celebrates Lowell's third marriage. Most of the poems in this book are new.

The three volumes contain many beautiful passages and throw an interesting sidelight on Lowell's methods of composition but the majority of the poems still seem rather unfinished. This may be because we have to accustom ourselves to Lowell's new development of the sonnet form.

Sylvia Plath (1932–63).

The Colossus, 1960; *Ariel*, 1965; *Crossing the Water*; *Winter Trees*, 1971. (Faber).

Sylvia Plath was an American of German ancestry. At the age of nine she suffered a traumatic shock with the death of her beloved father, a professor of biology at the University of Boston. Her adult attempts to come to terms with this overwhelming loss inspired some of her most powerful poems.

After a brilliant academic career in America and England, Plath married the English poet Ted Hughes (*q.v.*). The accounts of her premature death which were published recently by A. Alvarez have been disputed by Plath's husband and sister-in-law and, in any case, offer no new insights into her poetry.

The Colossus was the only one of Plath's books of poems to be published in her lifetime. The rest of her work has not appeared in the order of its composition. The poems of *Crossing the Water* predate those in *Winter Trees* and *Ariel*.

Plath spoke dismissively of the poems in *The Colossus*, which, unlike her subsequent ones, were not written to be read aloud and are rather monotonous in tone, although technically highly accomplished. The most important influence upon her writing was the publication of Lowell's *Life Studies* (*q.v.*). She admired these poems for the bold way they dealt with painful personal experience and she proceeded to emulate Lowell's achievement, but her work remains wholly individual in style and tone.

Like all poets, she has power to make us see the world as if for the first time, to enhance our awareness of life. She writes of poppies "wrinkly and clear red, like the skin of a mouth," and bells that "soberly bong out their names." Her world has the clarity of a primitive painting, but the poems of *Ariel* make almost intolerably painful reading for they express the heightened vision and self-mockery, the frangible control of utter hopelessness. Their images are often grotesque and full of menace:

> "Dawn gilds the farmers like pigs,
> Swaying slightly in their thick suits,
>
> White towers of Smithfield ahead."
> (*Totem*).

The moon far from being a symbol of serene agape is a face

> "White as a knuckle and terribly upset.
> It drags the sea after it like a dark crime; it is quiet
> With the O-gape of complete despair."
> (*The Moon and the Yew Tree*).

Plath's world is starkly coloured in red, black, white and the yellow of decay. She combines these images with allied symbols of energy, death and living death: blood, the yew, moonlight, the winding-sheet and the pupa. Her poems are haunted by a black father-figure, the Nazi "panzer man" of *Daddy*. The power with which she expresses her anguished vision derives partly from the simplicity of her metres and verse forms, which often have the insistent quality of nursery rhyme.

Poems like *Daddy* and the allied *Lady Lazarus* are unlikely to be forgotten, but in future others, such as the title poem of *Ariel* and *The Arrival of the Bee Box*, *Sting*, and *Elm* may be valued more highly. Our judgment is distorted by Plath's recent death and the knowledge that the harrowing poems of *Ariel* were the prelude to her suicide.

Anne Sexton (b. 1928).

Anne Sexton began writing in 1957. *Selected Poems*, 1964, *Love Poems*, 1969, and *Transformations*, 1972, have been published in England by the Oxford University Press, *The Book of Folly*, 1973, by Chatto & Windus. She acknowledges a debt to Lowell and deals with the same kind of subject as Sylvia Plath.

John Berryman (1914–72).

Homage to Mistress Bradstreet, 1956; *77 Dream Songs*, 1964; *Berryman's Sonnets*, 1967; *His Toy, His Dream, His Rest*, 1969; *Love and Fame*, 1971; *Delusions, Etc.*, 1972. (Faber).

Berryman was the most distinguished of those poets to whom the label "confessional" applied in its more general sense. Technically he was most inventive and ingenious and his work expressed enormous vitality, but some critics have found it undisciplined and pretentious and it is indeed true that only in *Homage to Mistress Bradstreet* did Berryman achieve objective expression of his themes.

His earliest work includes the poems published in 1967 under the title *Berryman's Sonnets*. This sequence, written during the 1940s, deals with an unhappy love affair.

Berryman began as a disciple of Yeats. Later, before gradually finding his own voice, he was influenced by the colloquial style of Auden. His earlier experiments found fruition in the extraordinary *Homage to Mistress Bradstreet*, which the eminent American critic Edmund Wilson considers to be the finest long poem since Eliot's *The Waste Land*. It is interesting that Berryman made a conscious effort to produce a work wholly unlike Eliot's masterpiece, and gave his poem a narrative framework and composed it in regular, though unusual, metrical stanzas. The form of these stanzas was inspired by the one Yeats evolved for his *In Memory of Major Robert Gregory*. Berryman uses an iambic metre (*see* M59) and the eight lines of his stanza have respectively five, six, three, four, five, five, three and six feet. The first and last lines rhyme and the fifth and sixth form an heroic couplet (*see* M60).

The poem's theme is the frustrations of the creative writer in an hostile, life-denying environment. This is expressed through a recreation of the life and personality of the Puritan immigrant Anne Bradstreet, who is sometimes called the first American poet.

The work is divided into five sections. The brief opening prologue, or "exordium" and closing "coda" are spoken by the modern poet. The second and fourth sections are monologues by Anne Bradstreet, while in the third the two speakers engage in broken dialogue. The overall effect is of a conversation between two aspects of the same personality.

Berryman brilliantly evokes the harshness of the Puritan settlers' "barbarous" life; the rigour of its winters, "white air lashing high"; the "ruinous heat" of its summers. These exterior conditions are paralleled by the Puritans' "chapped souls" and "starched minds"; by rheumatic fever and religious fanaticism. Against these physical and spiritual limitations Mistress Bradstreet struggles to be true to her own, kindly, creative vision.

In *77 Dream Songs* and *His Toy, His Dream, His Rest* Berryman develops the techniques he used in the earlier work to present multiple facets of a protagonist called Henry, "a white American in early middle age, who has suffered an irrevocable loss." These two books form a single work of three hundred and eighty-five lyrics. Together they present a kind of open-ended *Odyssey* of contemporary American life. They are often very amusing, often intensely irritating and their allusions to American society sometimes make them difficult for the English reader to follow, but they are compulsive reading and individual Songs, the painful 29 and 53 and the grotesque 91, for example, remain fixed in our minds.

In the anecdotal *Love and Fame*, Berryman writes in his own person, composing brief lyrics on the subject of his life and loves and his pursuit of fame. The style is loose, rambling and self-absorbed, yet there are flashes of his characteristic and engaging humour here and in the lyrics and elegies, interposed with anguished prayers, which make up Berryman's last volume, *Delusions, Etc.*.

11. Conclusion.

Readers who are spurred by their study of the poets discussed here and wish to explore further will discover much to enjoy in the work of writers to whom space precludes more than reference: Wilfred Owen, Robert Graves, Edwin Muir, R. S. Thomas, Peter Redgrove, Christopher Middleton, David Wright; the Americans Robert Frost, Theodore Roethke, Elizabeth Bishop and George Oppen. Penguin Books publish various useful anthologies. An excellent new paperback series is *Corgi Modern Poets in Focus*.

IV. ENGLISH VERSE PATTERNS

The patterns of its verse point and enhance a poem's significance. Some knowledge of the principles on which they are based can therefore help us towards a fuller enjoyment and appreciation of poetry.

The following account casts its net wide, covering verse designs as far apart in time as the Anglo-Saxon and the most up-to-date American forms. It is fully illustrated with quotations and with references to the numbered poems of *The New Oxford Book of English Verse* (OBEV) and *The Oxford Book of Twentieth Century English Verse* (OBTCV).

I. INTRODUCTION—SOME DEFINITIONS.

Verse and Prose.

The distinction between verse and prose has become blurred in our century, but we may safely say that in all verse the words are arranged so as to fall into more or less regular musical and, or, visual patterns, whereas in prose they are not. For example, if we listen carefully to a spoken sentence, we notice that some syllables are emphasised. The conventional way of indicating this in writing is by placing an acute accent over the vowel of the stressed syllables. Unstressed syllables may be marked x as in the following sentences:

x x / / x x x / x / x /
It is some sort of a solution, after all.

x / x / x / x / x /
It is a part solution after all.

We may observe that in the first sentence the stressed and unstressed syllables fall haphazardly, while in the second they form a pattern. The first, unpatterned sentence is deemed prose, the second, patterned one, verse.

The designs of verse are almost infinitely variable and although, as it stands, alone, the unpatterned sentence is not verse, it could be incorporated into a poem and so become an element in its design. Poets are constantly modifying existing verse forms and sometimes invent entirely new ones, aural and visual.

While some reference will be made to the visual designs, this article will be chiefly concerned with the aural patterns of verse, which have been, and still are, exploited by most poets. Visual patterns, where not entirely arbitrary or whimsical,

are either dependent on the musical ones or are individually determined by the poem's theme, which they are designed to reflect and enhance. They are therefore less susceptible to illustration and discussion within the compass of a short general article.

Metre.

Metre and Rhythm.

The word *metre* means a measure or rhythmical pattern. Verse originated in song, chant and invocation and its basic patterns are rhythmical. They may be founded on patterns of accent (stress), of single syllables, of cadences or lines.

Different Kinds of Metre.

Accentual verse: is written in accentual metre, a rhythmic pattern of accents or stresses.

Syllabic verse: is written in *syllabic metre*, a rhythmic pattern of syllables alone.

Accentual-syllabic or Metrical verse: is written in either *Iambic*, *Trochaic Dactyllic*, *Anapaestic*, *Amphibrach* or *Choriambic* metre. These metres, whose names are derived from those of Classical verse, will be further described. They are composed of regularly patterned groups of stressed and unstressed syllables, hence the name accentual-syllabic.

Quantitative Metrical verse: is usually written in one or other of six metres, also given the names *Iambic*, *Trochaic*, etc., quoted above. They are regularly patterned groups of long and short syllables and are the metres of Classical Greek and Latin verse. They are seldom used in English.

Free verse or *vers libre:* so called because it has no particular metre and is based on loosely patterned rhythms determined by the cadences of the speaking voice.

The Foot.

In some poetry the verse line is divided into groups of stressed and unstressed syllables, analogous to the bars in music. Such groups are known as feet. The line

" When you/shall see/me in/the toils/of Time" /
[OBTCV 2]

contains five feet, each comprising two syllables, unstressed followed by stressed.

The Caesura.

A long pause occurring at or about the middle of a line and usually indicated by a pause in the sense *e.g.*,

" Hearing one saga,//we enact the next "
[OBTCV 493]

The Verse and the Stanza.

Some poems are divided into groups of lines often called verses. Strictly speaking, *verse* is another name for the single line. A group of lines or verse is properly called a *stanza*. Generally the stanzas of a poem are uniform, but sometimes they are varied, as in Milton's " Lycidas "
[OBEV 304].

Rhyme.

Another formal pattern is created by the use of rhyme which can be at once visual and aural, though some kinds of rhyme appeal only to the eye, others chiefly to the ear. Rhymed words normally occur at the ends of lines.

In true rhyme the last stressed vowels and the letters following them are the same, while the letters preceding the stressed vowels are different, *e.g.*, cage/page; pleasure/treasure.

Alliteration.

The repetition of the same initial consonant, as in

" Full fathom five thy father lies "
[OBEV 130].

In some verse, most notably Anglo-Saxon narrative verse, alliteration is used instead of rhyme, but the two can be, and often are, combined.

Assonance.

A similarity between vowel sounds, *e.g.*, feet/creep; skin/swim.

Assonance is sometimes used instead of rhyme and occurs frequently in early folk poetry and informal verse.

II. DIFFERENT KINDS OF VERSE.

Accentual Verse.

Here the poet organises his verse according to a given number of stressed syllables in each line. The number of unstressed syllables varies.

Anglo-Saxon Verse.

This was written in an accentual metre in which each half-line contained two heavy stresses, the halves being linked by the alliteration of three of the stressed words. This kind of metrical form survived in such West Midland narrative poems of the fourteenth-century as Langland's " Piers Ploughman " and the anonymous " Sir Gawayne and the Grene Knight ", from which the following example is taken:

" There passes non bi that place so proude in his armes
That he ne dynges hym to deth with dynte of his honde:"

Nineteenth-Century Romantic Verse.

Coleridge experimented with accentual metre and for his " Christabel " chose a line of four stressed syllables and between three and eight unstressed ones:

A snake's small eye blinks dull and sly
And the lady's eyes they shrank in her head
Each shrunk up to a serpent's eye."

Sir Walter Scott, acknowledging a debt to Coleridge, chose a similar metre for " The Lay of the Last Minstrel ".

Sprung Rhythm.

For his sonnets, Gerard Manley Hopkins devised an accentual metre which he called *sprung rhythm* and described in the preface to his *Collected Poems* (1918).

The basis of sprung rhythm, which follows the natural rhythms of speech, is a line of usually five or six feet. Each foot contains between one and four syllables and extra unstressed syllables may be added for " particular effects " and at the beginning or end of a line. The first syllable of each foot is stressed:

" Gener/ations have/trod, have/trod;
And/all is/seared with/trade;/bleared,/smeared/ with/toil;
And/wears/man's/smudge and shares man's/ smell: the/soil/
Is/bare/now,/nor can foot/feel, being/shod. "
[OBEV 724]

Modern Acentual Metres.

Pound and Eliot are the modern masters of accentual metres. Examples of Pound's treatment may be found in " The River Merchant's Wife " and " Hugh Selwyn Mauberly," (OBEV 812–13). Pound's occasional division of a line, placing

the second part below and to the right of the first, so as to introduce a marked "rest", is a practice much imitated by modern American writers of free verse (*q.v.*), and their followers. In this example Pound divides a line of six stresses:

"What thou lovest well remains
the rest is dross".
[OBEV 814]

In poems such as "The Waste Land" [OBEV 828] and "Four Quartets" Eliot chose a basic metre of, say, four stresses, for one part of his poem, *e.g.*, the opening of "The Waste Land", and another, of, say, six stresses, for a different section. Within each section, moreover, he constantly modulated his pattern to reflect changes in the tone from one verse paragraph to another and even within each paragraph introduced occasional modifications and half-lines, the result being a metrical form of great subtlety and beauty. The following are typical examples of Eliot's use of regular and modified accentual metres:

Regular:

"Time present and time past
Are both perhaps present in time future
And time future contained in time past.
If all time is eternally present
All time is unredeemable."
"Burnt Norton".

Modified:

"The river sweats
Oil and tar
The barges drift
With the turning tide
Red sails
Wide
To leeward, swing on the heavy spar"
[OBEV 828]

Syllabic Verse.

Writers of syllabic verse vary widely in their aims and practice. The reader is therefore referred to two issues of the magazine *Agenda*, Vol. 10 No. 4 and Vol. 11 No. 1 (double issue 1973) and Vol. 11 Nos. 2 & 3 (double issue 1974). These contain various leading British and American poets' accounts of their own understanding of syllabics. Roy Fuller's lecture "An Artifice of Versification" (*Oxford Lectures on Poetry*, 1971) is also helpful.

Basic Syllabics.

English syllabic verse was pioneered independently, but at roughly the same time, during the First World War, by the British Elizabeth Daryush and the American Marianne Moore. Its basis is a given number of syllables to the line, disregarding the number and arrangement of stresses. In the following example the lines have each six syllables:

"you've seen a strawberry
that's had a struggle; yet
was, where the fragments met,"
Marianne Moore: "Nevertheless".

These lines also illustrate the common practice in syllabic verse of beginning all lines in lower case, which is felt to be less artificial than the conventional use of upper case.

Syllabic metre is natural to verse in French, but in a language such as English, where many words have feminine endings (*i.e.*, end on an unstressed syllable), it is difficult to use syllabic metres artfully.

The writer has to consider the following points:

Elision:

In spoken English some unstressed vowels are naturally elided, *e.g.*, the final "e" of learned. The poet must decide whether or not to count such elided syllables. Practice varies.

Poets such as Auden chose to make a nominal elision of certain syllables when writing but include them when the line is read aloud. Auden followed the Latin practice of eliding contiguous vowels separated by the letters "h" or "w" when counting syllables. Thus, "how elevating" would count as four syllables but be pronounced as five.

Line endings:

An obvious problem is that the strictly metrical line may end on an unimportant word, on an unstressed syllable or even in the middle of a word such as "happy" leaving the second syllable, "py", to be carried over. Thus the line may seem boneless. Further, although on the page there is a difference between, say, three lines each of six syllables and two lines each of nine, there may be no audible difference. Poets have tackled these problems in various ways.

The first is by virtually ignoring them, usually with unhappy result. Some writers say that the reader should not pause automatically at the ends of lines, but only where the punctuation indicates a pause. This is measurement by cadence rather than by syllable and such verse is often really chopped-up free verse (*q.v.*).

Skilful practitioners such as Moore, Daryush and Auden treat the problems as a challenge and shape their verses by apt use of end-stopped lines, by carefully placing important words at the line's end and by employing rhyme. Auden used all three devices in his poem "In Memory of Sigmund Freud", which is written in quatrains (*q.v.*) of 11, 11, 8 and 10 syllables:

"For one who lived among enemies so long:
If often he was wrong and at times absurd
To us he is no more a person
Now but a whole climate of opinion."

Accentual-Syllabic or Metrical Verse.

The traditional verse of English poetry is based on regular patterns of stressed and syllables grouped into feet.

English metrical verse uses several kinds of feet, some of two syllables, or disyllabic, some of three syllables or trisyllabic, and occasionally a foot of four syllables.

Disyllabic feet are of four kinds:

The Iamb, consisting of an unstressed syllable followed by a stressed, *e.g.* "return".
The Trochee, consisting of a stressed syllable followed by an unstressed, *e.g.*, "river".
The Spondee, consisting of two stressed syllables, *e.g.*, "door mat".
The Pyrrhic, consisting of two unstressed syllables, *e.g.*, in the phrase "into town", "into" is a pyrrhic.

Trisyllabic feet are of four kinds:

The Anapaest, consisting of two unstressed syllables followed by a stressed, *e.g.*, "as you wish".
The Dactyl, consisting of a stressed syllable followed by two unstressed, *e.g.*, "archery".
The Amphibrach, very rarely used, consisting of a stressed syllable between two unstressed, *e.g.*, "delighted".
The Tribrach, still more rare, consisting of three unstressed syllables *e.g.*, last three syllables of "incommunicable".

A four-syllabled foot is very occasionally found:

The Choriambus, which may be thought of as a trochee followed by an iamb, *e.g.*, "Toll for the brave".

Different Kinds of Metrical Line.

Based on the different kinds of feet are the different kinds of English metre, which may be compared with the "time" in music.

Disyllabic metres may be either iambic or trochaic, for it is impossible to speak at any length using only pyrrhic or spondees, and the most common trisyllabic metres are anapaestic or dactyllic. Examples of different kinds of metrical line follow.

Iambic Line.

"I stróve with nóne, for nóne was wórth my strife."
[OBEV 521]

Trochaic Line.

"Hóme art góne, and tá'en thy wáges."
[OBEV 127]

Anapaestic Line.

"With a héy, and a hó, and a héy noninó,"
[OBEV 122]

Dactylic Lines.

"Wit with his wántonness
Tásteth death's bitterness;"
[OBEV 85]

Amphibrach Lines.

"Most friendship is feigning, most lóving mere fólly.
Then héigh-ho! the hólly!
This life is most jólly." [OBEV 121]

Choriambic Line.

"Kéntish Sir Bẏng stọod for his King."

Variations in Metre.

Satisfying poetry is rarely entirely regular. Mechanical regularity is soon wearisome to the ear and is a characteristic doggerel. The poet satisfies our love of rhythm in a more interesting and subtle way by introducing all kinds of variations and inversions, while at the same time maintaining the throb of the basic metre. An account of the chief variations follows.

Elision.

Elision, as explained above, is the suppression of pronunciation of a vowel or a syllable.

In the anapaestic line,

"The Assẏrian came dówn like a wólf on the fóld."

the second foot appears to have four syllables, but in fact the "i" of "Assẏrian" is elided or dropped before the "a" as shown by the caret mark ˚. The elision of "i," which is pronounced "y" and known as "consonantal y" is especially common, and occurs in such words as "familiar", "opinion". Elision is often shown by the use of the apostrophe as in "heav'n". In "heav'n" we see one of the many conventional elisions of poetry, like "'tis", "'twas", "did'st", "o'er", "'gainst" and many more.

Substitution.

Substitution is the use of a foot different from that of the metre in which the poem is written. In the following examples we can see the effect on iambic verse of some common substitutions.

(i) *Of a Trochee.*

"Stiffen the sinews, súmmon úp the blóod,"
Shakespeare, "Henry V."

Here the initial trochee gives force and emphasis.

(ii) *Of a Spondee.*

"Rócks, cáves, lákes, féns, bógs, déns, and shádes of déath."

In this extraordinary line of Milton's the spondees slow down and weight the verse.

(iii) *Of a Pyrrhic.*

"They flẏ forgótten as a dréam"

Here the pyrrhic in the third foot gives lightness to the line.

(iv) *Of a Dactyl.*

"Shrieking his bálefull nóte, which éver dráve"
[OBEV 58]

When a dactyl replaces an iamb it is usually in the first foot as in this typical instance from Spenser, where the dactyl gives emphasis and variety to the line.

(v) *Of Anapaests.*

"And the cóming wind did róar more lóud,
And the sáils did sigh like sédge;"
[OBEV 509]

The initial anapaests in these two lines from "The Ancient Mariner" give an effect of hurry and speed.

Additional Syllable.

An additional syllable may be added to either the beginning or end of a line.

(i) *Feminine Ending.*

A feminine ending is an extra unstressed syllable that is added after the final stressed syllable of a line, giving a gentle falling inflexion. It is often used in blank verse and is a marked characteristic of Shakespeare's later plays, *e.g.*,

"Be not afear'd; the isle is full of noises,
Sounds and sweet airs, that give delight, and hurt not."

(ii) *Anacrusis.*

Anacrusis is the use of an extra syllable before the first regular foot of the line.

Dropped Syllable.

It sometimes appears that a line is a syllable, or syllables, short, until we realise that a suspense or pause occupies the time that would have been taken by the missing syllable. The dropped syllable can be indicated by the caret mark ˚. The following technical terms are used for lines that are short of syllables.

(i) *Catalectic Line.*

This leaves off in the middle of the last foot, as in the trochaic line

"Éver lét the fáncy róam,"

or the dactylic line,

"Rings on her fingers and bélls on her tóes,"

The catalectic line is common in trochaic and dactylic verse, for it is in keeping with the tendency of English verse to end on a stressed syllable.

(ii) *Acephalous Line.*

This omits the first syllable of the line, as in the anapaestic line,

"That hóst with their bánners at súnset were séen."

Iambic Metres.

The metre most natural to the English language is undoubtedly the iambic.

With Iambic Pentameter as Basis.

The iambic pentameter of five stresses and ten syllables, also called the iambic decasyllabic line is more used than any other, and is the basis of the following forms.

(i) *Blank Verse.* Blank verse, consisting of unrhymed iambic pentameters, is the metre of Shakespeare's plays, Milton's "Paradise Lost", Wordsworth's "Prelude", and Tennyson's

"Idylls of the King". In the hands of such masters it is a most flexible instrument especially when diversified with the eleven-syllabled line with a feminine ending. Shakespeare used the metre with increasing freedom, though it must be remembered that some apparent variations are due to the different pronunciation of Elizabethan times.

The following lines of blank verse occur in Wordsworth's "Prelude", Book III. He is describing his rooms in St. John's College, Cambridge.

"And from my pillow, looking forth by light
Of moon or favouring stars, I could behold
The antechapel where the statue stood
Of Newton with his prism and silent face,
The marble index of a mind for ever
Voyaging through strange seas of Thought,
alone."

(ii) *Heroic Couplet.* The heroic couplet, consisting of iambic pentameters rhyming in pairs, was in Elizabethan times called "riding rhyme", possibly because it is the metre of The Prologue of Chaucer's "Canterbury Tales", and of many of the tales themselves. It became the most fashionable metre of the eighteenth century when it was used by Pope, Goldsmith, and Johnson. Keats later employed it in "Lamia."

The *Closed Couplet* was, in the heyday of the couplet's vogue, considered the most polished and correct. Here the sentence form exactly coincides with the couplet and the rhyme has a clinching effect, *e.g.*,

"True ease in writing comes from art, not chance,
As they move easiest who have learned to
dance."

Pope was the supreme master of the closed couplet, and eschewed variations such as enjambment, or the Alexandrine.

Enjambment is a variation used by poets before Pope's time and revived by the Romantic poets. In enjambment the sentence flows over from one line or couplet to the next, and the click of the rhyme is submerged, *e.g.*, Keats' description of Lamia in her serpent form with skin of "dazzling hue".

'And full of silver moons, that, as she breathed
Dissolv'd or brighter shone, or interwreathed
Their lustres with the gloomier tapestries."
Keats, "Lamia".

The Alexandrine, another variation, is a line of six iambic feet. Dryden made frequent use of the Alexandrine but Pope parodied it in the brilliant line that serves as a mnemonic:

"A needless Alexandrine ends the song,
That, like a wounded snake, drags its slow length
along."

The triplet, another variation, consists of three lines rhyming together. The third line is frequently an Alexandrine.

Other Iambic Metres.

Many of our iambic verse forms use a shorter or longer line than the pentameter.

(i) *The Octosyllabic Couplet.* The octosyllabic couplet consists of lines of four stresses and eight syllables, and the lines rhyme in pairs. English poets like Marvell have used this metre effectively, *e.g.*, "The Garden" [OBEV 338, *see also* OBEV 337, 370]. It is the metre of Masefield's "Everlasting Mercy" and "Reynard the Fox".

(ii) *Double Iambic Metre.* When we are accustomed to hearing verse we come to realise that stresses are not always of equal weight. It is possible to distinguish in these "fourteeners" of Masefield a major stress, marked ˝ and a minor stress marked ˊ.

"Oh sóme are fónd of Spánish wine, and sóme are
fónd of Frénch,
And sóme'll swállow táy and stúff fit ónly
fór a wénch."
Masefield's "Captain Stratton's Fancy"

The lines have in fact four major stresses, and between the major stresses intervene three syllables, of which the middle has a minor stress. It is this alternation in the weight of the stress which gives its characteristic swing to such a poem as Chesterton's "The Rolling English Road" [OBEV 796].

Trochaic Metres.

Pure Trochaic Metre.

English poets seldom use a pure trochaic metre, partly because the continual feminine ending that it involves is not pleasing to the English ear. A few very short lyrics in this metre can be found, as Browne's Song "For her gait, if she be walking", but the only poem of any length is Longfellow's "Hiawatha", and the metre of this *tour de force* tends to sound monotonous. It consists of unrhymed lines, each of four stresses, *e.g.*,

"Like a yéllow léaf in áutumn
Like a yéllow wáter-lily."

Modified Trochaic Metre.

Ever since the Middle Ages our poets have contrived to combine the advantages of a trochaic metre and of a masculine ending by the simple expedient of shortening the last foot of the line to a stressed monosyllable. This catalectic, or shortened, trochaic line is found both in couplets and in stanza forms. *The seven-syllabled trochaic couplet, also called the trochaic tetrameter*, consists of these catalectic, or shortened, lines rhyming in pairs, and is a gay, tripping measure, as in some passages of Milton's "L'Allegro".

"Háste thee nýmph and bríng with thée
Jést and yóuthful jóllity,"

In "Locksley Hall" Tennyson uses a fifteen-syllabled couplet, the last foot being catalectic, while a sixteen-syllabled trochaic line is used by E. A. Poe in his "Raven". Here each line is divided into halves by the caesura and the halves also rhyme:

"Ah, distinctly I remember, it was the bleak
December."

Lyrics in modified trochaic metre are often found. Herrick uses the seven-syllabled lines rhyming in pairs in "Cherry Ripe", Wither in "A Lover's Resolution" [OBEV 245]. Edmund Blunden, in "Forefathers" [OBEV 843], uses it in a stanza rhyming ABABCC. George Herbert in his lyric "Discipline" [OBEV 276] brilliantly combines five- and three-syllabled lines rhyming ABAB, *e.g.*,

"Thrów awáy Thy ród,
Thrów awáy Thy wráth;
Ó my Gód,
Táke the géntle páth."

Further Variations in Modified Trochaic Metre.

The modified trochaic line is especially subject to further variation.

(*a*) It is often combined with a pure trochaic line, *e.g.*, in Hunt's poem "Jenny Kiss'd Me" [OBEV 600] where the catalectic and the complete trochaic line alternate regularly.

(*b*) It often has an extra unstressed syllable preceding it (anacrusis), as in the second of these lines from Keats' poem "Fancy".

"In a dárk conspíracy
To | bánish Éven fróm her sky."

The line that results might well be taken for iambic, and there are some passages in English poetry, such as lines in Milton's "L'Allegro", which can be described either as irregular trochaic or irregular iambic lines! It depends on what the hearer judges to be the *basic* stress.

Double Trochaic Metre.

Corresponding to double iambic metre there is a double trochaic metre. W. S. Gilbert effectively uses it in many of his patter songs, as in "Ferdinando and Elvira", *e.g.*,

"Thén we lĕt off páper crăckers, eách of which
contáined a mótto,
Ánd she listened while I rĕad them, till her
móther tóld her nŏt to."

These lines, like those in double iambic metre, have four major stresses (marked ″), and between the major stresses three syllables, of which the middle carries a minor stress.

A modified double trochaic metre, where the last foot is shortened to a stressed monosyllable, can be recognised in Tennyson's "Locksley Hall", or in Lewis Carroll's verses in "Alice in Wonderland":

"'Will you wălk a little fástĕr?' sáid a whíting
tó a snáil."

Trisyllabic Metres Generally.

Because of the irregularities incident to verse in anapaests, dactyls, and amphibrachs, it is not easy to distinguish one trisyllabic metre from another. Swinburne, the past master of trisyllabic metres, often passes with great freedom from anapaestic to dactylic lines within the same stanza.

Anapaestic Metres.

Anapaestic metre is used only in short poems, and often conveys a sense of speed and urgency. The chief variation is the omission of one or two of the unstressed syllables at the beginning of a line. Some of the best-known examples of anapaestic verse are Byron's "Sennacherib", Flecker's "The War Song of the Saracens", and Lewis Carroll's parodies, "'Tis the voice of the lobster", and "You are old, Father William", from *Alice in Wonderland*.

Dactylic Metres.

Pure Dactylic Metre.

Like pure trochaic metre, pure dactylic metre has a feminine ending to the line, which makes rhyming difficult and does not satisfy the English ear. Very few serious poems keep consistently to a pure dactylic verse, and Robert Graves' "In the Wilderness" is most unusual in this respect, *e.g.*,

"Christ of His gĕntleness
Thirsting and hŭngering
Wálked in the wilderness."

Modified Dactylic Metre.

Normally dactylic metre is modified in that a catalectic line is frequently used, where the final foot is shortened to a trochee or a stressed monosyllable, as in Hood's "Bridge of Sighs", the most remarkable dactylic poem in the language, *e.g.*,

"Óne more Unfórtunate
Wéary of bréath
Ráshly impórtunate,
Góne to her déath!"

Shakespeare also uses the catalectic line in the refrain to "Where the bee sucks" [OBEV 131]—

"Mérrily mérrily sháll I live nów
Under the blóssom that hángs on the bóugh."

It is interesting to note how the catalectic dactylic line of the refrain is matched by the catalectic trochaic line of the verse.

Amphibrach Metres.

Pure Amphibrach Metre.

The amphibrach metre is extremely rare in English, although it occurs occasionally in a few lines, or a refrain, like that to "Blow, blow thou Winter Wind" [OBEV 121]. Laurence Binyon's "Bablock Hythe" is one of the few poems to use amphibrachs continuously, *e.g.*,

"Till súnset was rímming
The Wést with pale flúshes;
Behínd the black rúshes
The lást light was dímming."

Modified Amphibrach metre.

The pure amphibrach line can be used alternating with a catalectic line, shorn of its last syllable, as in Goldsmith's drinking song in "She Stoops to Conquer", Act I, Scene 2, *e.g.*,

"Let schóol-masters púzzle their bráin
With grámmar and nónsense and léarning."

Choriambic Metres.

There are few poems in pure choriambic metre. Ruskin's quatrain "Trust Thou thy Love" is one of the few examples, *e.g.*,

"Trúst thou thy Lóve; if she be próud, is she not
swéet?"

Choriambic effects are often obtained incidentally especially in blank verse, when the first foot of a line is a trochee.

Lionel Johnson frequently achieves the same kind of effect in lyric verses by substituting a choriamb for two iambs, as in the poem "By the Statue of King Charles" [OBEV 757], *e.g.*,

"Cómely and cálm, he rides
Hárd by his ówn Whitehall:"

Quantitative Verse.

Since the Renaissance poets such as Spenser, Coleridge, and Tennyson have from time to time endeavoured to reproduce in English verse the complicated quantitative measures of Greek and Latin verse. The difficulty, if not impossibility, of putting the stress on the long vowel in English has for the most part rendered such experiments interesting only to the scholar.

It should always be remembered that the technical names, such as iamb and trochee, although borrowed from the classics, have in English verse a quite different meaning, referring never to quantity but always to stress.

Free Verse or *Vers Libre*.

The prosody of free verse is extremely complicated. The following note offers only a very general guide.

The free verse or *vers libre* of English and American poetry has two sources, the poems of Walt Whitman and of the French Symbolists, particularly as interpreted by Pound. It is a verse designed in the cadences and breath groups of the speaking voice and given shape by a cunning use of four rhetorical devices: repetition, parallelism—balancing one phrase or line against another, enjambment—run-on lines, and pauses.

Repetition and Parallelism.

These devices are characteristic of much ancient poetry and may be familar to the reader from the Old Testament Psalms, which are written in free verse:

"He giveth snow like wool: he scattereth the
hoar-frost like ashes.
He casteth forth his ice like morsels: who
can stand before his cold?"
Psalm 147.

Whitman's verse recalls such translation of ancient Hebrew poetry in its deployment of rhetorical lists and repetitions, balancing one statement against another:

" Pleas'd with the native and pleas'd with the foreign, pleas'd
with the new and old,
Pleas'd with the homely woman as well as the handsome,
Pleas'd with the quakeress as she puts off her bonnet and
talks melodiously "
Whitman: " Song of Myself ".

In " Howl " and " Kaddish " Allen Ginsberg makes similar use of parallelism and repetition.

D. H. Lawrence in " Snake " [OBEV 810] and " Kangaroo " [OBTCV 184] shows how such free verse is modified for contemplative and narrative poems, in which the parallels and repetitions are more subtlely deployed:

" He reached down from a fissure in the earth-wall in
the gloom
And trailed his yellow-brown slackness soft-bellied
down, over the edge of the stone trough
And rested his throat upon the stone bottom,
And where the water had dripped from the tap, in a
small clearness,
He sipped with his straight mouth,
Softly drank through his straight gums, into his slack
long body,
Silently."
[OBEV 812]

Enjambment and Pause.

We will have noticed that the lines from Lawrence's poem owe much of their effectiveness to his adroit arrangement of pauses and of run-on lines. Other writers of free verse make particular use of these two devices, and poets like George Oppen create verses in which a complex musical pattern of pauses, or rests, is indicated by the very spacing of the words:

. . . . . Who
so poor the words

would with and take on substantial

meaning handholds footholds

to dig in one's heels sliding

hands and heels beyond the residential
lots the plots it is a poem

which may be sung
may well be sung
" The Winds of Downhill ".

Other writers, while making some use of such spacing, or of dashes, to indicate the rests, have developed Pound's device of breaking up the lines and placing one part below and to the right of another:

This was I,
a sparrow.
I did my best;
farewell.
W. C. Williams: " The Sparrow ".

III. THE DIFFERENT KINDS OF RHYME

The most familiar division of rhyme is into masculine, feminine, and triple rhyme, but we also distinguish broken and Leonine rhyme.

Masculine, Male or Single Rhyme.

The final syllable is stressed, *e.g.*, " cage/page " " joy/boy ".

Feminine, Female or Two-syllable Rhyme.

The syllable before the last is stressed, and the final syllable unstressed, *e.g.*, " pleasure/treasure ". " bending/lending ".

Triple, Tumbling or Three-syllabled Rhyme.

The antepenultimate syllable is stressed. Triple rhyme is normally found in light or comic verse, like that of W. S. Gilbert. This punning " Epitaph on a Dentist " employs it:

" Stranger! Approach this spot with gravity!
John Brown is filling his last cavity."

In " The Bridge of Sighs " Hood dares to use it in a serious poem with such rhymes as " scrútiny/mútiny ".

Broken Rhyme.

Broken rhyme, where more than one word is needed to complete the rhyme, is occasionally used, *e.g.*, " estate/their gate ".

Leonine Rhyme.

Although rhyme normally occurs at the end of the line, we also find verse where the first half of the line rhymes with the second. This device, known as Leonine rhyme, is frequently used in Coleridge's " Ancient Mariner " [OBEV 509], *e.g.*,

" The ice did split, with a thunder-fit: "

Poetic Licence in Rhyme.

The difficulty of rhyming in English is considerable, for many words have not a single rhyming word, some have only one, others very few. Certain licences are therefore allowed to the poet in the following ways:

Eye Rhyme or Printer's Rhyme.

Here words rhyme only to the eye, as " love/move ". Keats in " Meg Merrilies " uses " rushes/bushes ".

Identical Rhyme.

Here the same syllable or word is used twice so that the line rhymes with itself, *e.g.*, " universe/this verse " [OBEV 549]. The use of rhyming words spelt differently but pronounced identically is also a poetic licence, *e.g.*, " wright, write, right ".

Cockney Rhyme.

Keats' use of Cockney rhymes has been much criticised, *e.g.*, " mourn/torn ", " faces/vases " " briar/attire ". There is still considerable difference between regional pronunciation of English, and many eminent poets have availed themselves of a Southern pronunciation in rhyming " dawn/morn ", although in some districts the " r " of " mourn " would be sounded.

Perversion of Rhyme.

Modern poets, following Wilfred Owen, have sometimes used a deliberate perversion of rhyme, which should not be confused with assonance. Wilfred Owen opens his bitter poem " A Terre " with the following stanza:

" Sit on the bed. I'm blind and three parts shell.
Be careful; can't shake hands now; never shall.
Both arms have mutinied against me,—brutes.
My fingers fidget like ten idle brats."

The deliberate falsity of rhymes like " shall/shell," and " brutes/brats " conveys Owen's horror at the disintegration and collapse of the First World War.

The Recording of Rhyme Schemes.

The conventional way of noting rhyme schemes is to call the first series *a*, the second *b*, and so on. Normally each new series is indented, *e.g.*,

"Joyful, joyful!	*a*
When virginity	*b*
Seeks all coyful	*a*
Man's affinity.	*b*
Fate all flowery,	*c*
Bright and bowery	*c*
Is her dowery!	*c*
Joyful, joyful."	*a*

W. S. Gilbert, "Yeomen of the Guard."

IV. STANZA FORMS

Two-Line Stanzas.

Couplets.

These are rhymed. Regular couplets are also closed, that is, the sense does not run over from one stanza to another.

In "The Knight and the Lady" [OBEV 20] Sir William Cornish uses a stanza of irregular octosyllabic iambic couplets, while Auden's "Roman Wall Blues" is an example of couplets written in an irregular accentual metre:

"Over the heather the wet wind blows
I've lice in my tunic and a cold in my nose."

Distiches.

These are unrhymed, but again the regular form is closed. John Wain's "Brooklyn Heights" [OBTCV 518] is an example of a poem written in distiches with an accentual metre of five stresses.

Three-Line Stanzas or Tercets.

There are various forms of which the most common are:

Triplets.

A three-line stanza with a single rhyme, AAA, BBB, etc., as in Robert Graves's "Sick Love" [OBEV 839] Roy Fuller's "The Statue" [OBEV 872].

Terza Rima.

The classic form, as used by Dante in the "Divine Comedy", has stanzas of three iambic pentameters linked by rhyme: ABA, BCB, CDC, etc., the concluding stanza having an extra line which rhymes with its middle one, *e.g.*, DEDE. A recent example of the form is Matthew Mitchell's "Printing Jenny" [OBTCV 533]. In "Ode to the West Wind" [OBEV 549] Shelley uses a modified *terza rima* in which the concluding stanza is a couplet. An interesting modification of the form is used by Auden in "If I Could Tell You" and "Miranda's Song". Each is a poem of six stanzas, the last a quatrain ending in a couplet. Only two rhymes are used throughout, ABA, the last stanzas rhyming ABAA.

In Italian the rhymes used in *terza rima* are feminine. English poets have generally preferred to use masculine rhymes.

Tercets with Short Third Lines.

These may be arranged in pairs, as in Herbert's "The British Church", where the rhyme scheme is AAB, CCB etc., resembling the sestet of a sonnet (*q.v.*) with a strong median pause.

Unrhymed Tercets.

An example is Ted Hughes's "Thistles" [OBTCV 550] composed of four unrhymed tercets in free verse.

Four-Line Stanzas or Quatrains.

A great many variations are possible. The most common forms include:

The Ballad Stanza.

There are two main forms:

Strict ballad form.

It consists of stanzas of four iambic lines, the first and third having four feet the second and fourth containing three. The rhyme scheme is ABCB. Ballads such as "Sir Patrick Spens" [OBEV 357] and "The Wife of Usher's Well" [OBEV 360] are in this form. Coleridge's "Ancient Mariner" [OBEV 509] shows how flexibly the ballad stanza can be used.

Less strict ballad form.

Octosyllabic iambic stanzas with a rhyme scheme of either ABCB or ABAB. Many ancient ballads, such as "Thomas the Rhymer" [OBEV 355] are of this type.

The Envelope or "In Memoriam" Stanza.

Used by Tennyson for his poem "In Memoriam" [OBEV 604–11] the stanza resembles that of the less strict ballad form in having four iambic lines, each of four feet, but its rhyme scheme is ABBA.

Hymns.

Most English hymns are written in short iambic lines, and English hymnology refers to them according to the number of syllables in their lines.

Common measure.

8686 rhyming ABAB, *e.g.*, "O for a thousand tongues to sing" (*Songs of Praise* 595).

Long measure.

8888 rhyming ABAB, *e.g.*, "When I survey the wondrous cross" (*Songs of Praise* 133).

Short measure.

6686 rhyming ABCB, *e.g.*, "Blest are the pure in heart" (*Songs of Praise* 455).

The Elegiac Stanza or Heroic Quatrain.

It consists of four iambic pentameters rhyming ABAB. The form is best known from Gray's "Elegy" [OBEV 429].

The "Jabberwocky" Stanza.

Used by Lewis Carroll for his nonsense verses "Jabberwocky" [OBEV 681] the stanza consists of four iambic lines, the first three of four feet, the final line of three. The rhyme scheme is ABAB.

The "Omar Khayyam" Stanza.

Named from its use by Edward Fitzgerald in translating the "Rubaiyát" [OBEV 594], the stanza has four iambic pentameters rhyming AABA.

Sapphics.

A quatrain based on the form used by the Greek poetess Sappho in her surviving ode. The first three lines are each of five feet: a trochee, a spondee, a dactyl, a trochee, a spondee. English writers generally prefer the following variation: dactyl, spondee, trochee, trochee, trochee.

The fourth line of the stanza contains but two feet. The Classic form is dactyl and spondee. In English Sapphics the line may be of a dactyl and trochee.

Isaac Watts's "The Day of Judgement" [OBEV 392] illustrates the form:

"When the fierce North-wind with his airy forces
Rears up the Baltic to a foaming fury;
And the red lightning with a storm of hail comes
Rushing down:"

Another example is Sir Henry Newbolt's famous "He Fell Among Thieves" [OBTCV 52].

Other Forms.

Another particularly interesting form is the stanza used by George Herbert in "Virtue" [OBEV 271] and by Sir Richard Fanshawe in "Ode on His Majesty's Proclamation" [OBEV 297]. It consists of three lines each of four iambics, followed by a line of two feet, again iambic. The rhyme scheme is ABAB.

Five-Line Stanzas or Quintains.

Although the quintain has been used by many poets in a variety of ways no particular form has become established. The quintain's lines often vary in length, as in this example from Hardy's "Old Furniture" [OBTCV 17]:

"I know not how it may be with others
Who sit amid relics of householdry
That date from the days of their mothers' mothers,
But well I know how it is with me
Continually."

Other interesting examples are the stanzas of Shakespeare's song "Who is Sylvia", Shelley's "Ode to a Skylark" [OBEV 550] Hugh MacDiarmid's "Cattle Show" [OBTCV 254] and Dylan Thomas's "The force . . ." [OBTCV 439]

Six-Line Stanzas or Sestets.

Again there are many examples and no definitive forms. A popular rhyme scheme is ABABCC giving the effect of a quatrain followed by a couplet. This is used with a stanza of six iambic pentameters in Marvell's "The Fair Singer" [OBEV 340] and Betjeman in "The Metropolitan Railway" [OBTCV 350]. Herbert's poem "Love" uses a more striking stanza:

"Love bade me welcome; yet my soul drew back
Guilty of dust and sin.
But quick-eyed Love, observing me grow slack
From my first entrance in,
Drew nearer to me, sweetly questioning,
If I lacked anything."
[OBEV 277]

Another interesting form is that used by Auden for his menacing chorus "We are the Town" [OBTCV 379].

Seven-Line Stanzas.

The only established form is

Rhyme Royal.

A stanza of seven iambic pentameters rhyming ABABBCC, this was used by Chaucer in "Troilus and Cressida" [OBEV 7 & 8] and by Shakespeare in "Lucrece" [OBEV 115].

Eight-Line Stanzas or Octaves.

Ottava Rima

A stanza of eight iambic pentameters rhyming ABABABCC, it was used by Byron in "Don Juan" [OBEV 543], by Keats in "Isabella" and Auden in "Letter to Lord Byron".

Other Octaves.

Many other forms exist in various combinations of metres and rhyme schemes, but none have become well known. Examples of interest include Fletcher's "Away Delights" [OBEV 223] Marvell's "The Picture of Little T. C. . . ." [OBEV 341], Hardy's "Voices from Things Growing in a Country Churchyard [OBTCV 31] and John Berryman's "Homage to Mistress Bradstreet".

The Nine-Line Stanza.

The Spenserian Stanza.

A stanza of eight iambic pentameters followed by an Alexandrine has a rhyme scheme of ABABBCBCC. It was invented by Spenser for his "Fairie Queene" [OBEV 58–63] and used by Byron in "Childe Harold" [OBEV 536–7], Shelley in "Adonais" [OBEV 552] and Burns in "The Cottar's Saturday Night".

Other Stanza Forms.

Stanzas of ten and more lines are used in many variations. Notable ones include those in Tennyson's "Mariana" [OBEV 595], Gray's "Ode on a Distant Prospect of Eton College" [OBEV 426] Donne's in "The Anniversary" [OBEV 195].

The Diagrammatic Stanza.

Some poets have delighted to create stanzas whose very appearance echoes their theme, as in Herbert's "Easter Wings":

"Lord, Who createdst man in wealth and store,
Though foolishly he lost the same,
Decaying more and more,
Till he became
Most poore:
With Thee
O let me rise
As larks, harmoniously,
And sing this day Thy victories:
Then shall the fall further the flight in me."

The second half of the poem repeats this pattern so that the whole has the shape of two pairs of wings. In the present century Dylan Thomas succeeded in creating an even more complex structure in his extraordinary "Vision and Prayer".

V. OTHER METRICAL FORMS

The Sonnet.

A sonnet has fourteen iambic pentameters. Perfected in Italy by Petrarch, who died in 1374, it was introduced into England in the sixteenth century. There are two chief types of sonnet.

The Petrarchan, or Italian, sonnet has an "octave" of eight lines, rhyming ABBAABBA, followed by a "sestet" of six lines, where some variety of rhyme schemes is found. The strictest Petrarchan sonnets have either two "tercets" of three lines each, with rhymes CDECDE, or else three pairs of lines rhyming CDCDCD.

An example of sestet rhyming CDECDE is Milton's "On His Blindness" [OBEV 305].

Examples of sestets CDCDCD are Wordsworth's "Upon Westminster Bridge" [OBEV 486] and Keats' "On First Looking into Chapman's Homer" [OBEV 562].

Not all of these examples observe the natural pause between octave and sestet which is characteristic of the strict Italian form, and many of our finest sonnets depart from the original rhyme scheme in both octave and sestet.

A lesser-known Petrarchan sonnet by Keats:

"To one, who has been long in city pent,
'Tis very sweet to look into the fair
And open face of heaven,—to breathe a prayer
Full in the smile of the blue firmament.
Who is more happy, when, with heart's content,
Fatigued he sinks into some pleasant lair
Of wavy grass, and reads a debonair
And gentle tale of love and languishment?
Returning home at evening with an ear
Catching the notes of Philomel,—an eye
Watching the sailing cloudlet's bright career,
He mourns that day so soon has glided by:
E'en like the passage of an angel's tear
That falls through the clear ether silently."

The Elizabethan or Shakespearean sonnet consists of three quatrains with the rhymes ABAB/CDCD/EFEF/ concluded by a couplet rhyming GG. The couplet often clinches the thought.

Examples are Shakespeare's sonnets [OBEV 134–153], and Keat's last sonnet [OBEV 571].

The Limerick.

The limerick may be defined as a single anapaestic stanza, having the first two lines of three feet, the next two lines of two feet and a concluding line of three feet, with the rhyme scheme AABBA.

The origin of the limerick is uncertain, but it became popular after the appearance in 1846 of Edward Lear's "Book of Nonsense". Lear's

limericks differ from the contemporary type in that his final line is normally a repetition, adding nothing to the sense and repeating one of the previous rhyme words.

Most of our modern limericks are passed on by word of mouth, but some that concisely express some intellectual attitudes have appeared in print as the following, on "Determinism"—

"There wás a young mán who said 'Damn!
It appéars to me nów that I ám
Just a béing that móves
In predéstinate gróoves,
Not a táxi or bús, but a trám.'"

The Clerihew.

The clerihew is an amusing quatrain, so called after its inventor Edmund Clerihew Bentley. It disdains regular metre and depends on the simple rhyme scheme AABB. The distinctive characteristic of the clerihew is that it is concerned with some eminent person, who is named in the first line and then described in a wilfully fanciful way, the matter being dictated by the exigencies of the rhyme, as in Bentley's clerihew on J. S. Mill.

John Stuart Mill,
By a mighty effort of will,
Overcame his natural bonhomie
And wrote 'Principles of Political Economy'.

Metrical Forms of French Origin.

It became fashionable during the last years of the nineteenth century for poets to imitate certain verse forms which had long been practised in France, some of them from the time of the troubadours.

Chaucer and Gower had in the fourteenth century used some of these forms, later English poets had occasionally experimented with some of them, and Swinburne, Austin Dobson, Edmund Gosse, and others did much to adapt and naturalise them, although their intricate rhyming patterns are so very difficult to construct in a language so short of rhymes as English. The most popular were the triolet, villanelle, rondeau, ballade, and sestina.

Characteristic of the Anglicised versions are:

1. Freedom as regards metre and length of line.
2. Complicated and exacting rhyme schemes, which permit of no such poetic licence as identical rhyme.
3. A refrain line which recurs in certain stereotyped positions without any alteration of sound, although there may be significant alteration of meaning. Only the sestina is without a refrain.

The Triolet.

A triolet is a single stanza of eight short lines. The first line is repeated as the fourth, and the first and second appear again as seventh and eighth. Only two rhymes are used, the scheme being ABAAABAB.

The triolet was re-introduced into England by Bridges in 1873. Austin Dobson's "A Kiss" is a good example of the form.

"Rose kissed me today.
Will she kiss me tomorrow?
Let it be as it may,
Rose kissed me today,
But the pleasure gives way
To a savour of sorrow;—
Rose kissed me today,—
Will she kiss me tomorrow?"

The Villanelle.

The villanelle has five stanzas, each of three lines, followed by one stanza of four lines. It has a refrain which consists of the first and third lines of the first stanza. These lines alternately form the last lines of the four middle stanzas, and reappear as a concluding couplet to the poem. Only two rhymes are employed throughout. Stanzas one to five rhyme ABA and stanza six ABBAA.

Austin Dobson wrote several villanelles including the well-known "On a Nankin Plate", and W. E. Henley's poem called "Villanelle" is a good example of the form. A modern example is:

A villanelle by Dylan Thomas:

Do not go gentle into that good night

"Do not go gentle into that good night,
Old age should burn and rave at close of day;
Rage, rage against the dying of the light.

Though wise men at their end know dark is right,
Because their words had forked no lightning they
Do not go gentle into that good night.

Good men, the last wave by, crying how bright
Their frail deeds might have danced in a green bay,
Rage, rage against the dying of the light.

Wild men who caught and sang the sun in flight,
And learn, too late, they grieved it on its way,
Do not go gentle into that good night.

Grave men, near death, who see with blinding sight
Blind eyes could blaze like meteors and be gay,
Rage, rage against the dying of the light.

And you, my father, there on the sad height,
Curse, bless, me now with your fierce tears, I pray.
Do not go gentle into that good night,
Rage, rage against the dying of the light."
[OBEV 882]

The Rondeau.

A rondeau is a short and compact verse form. It has thirteen lines, usually of eight syllables, which use only two rhymes, and in addition a refrain, usually of four syllables, which introduces a third rhyme. This refrain consists of the first half of the opening line and is twice repeated, thus giving the rondeau fifteen lines all told. The rondeau is divided into three stanzas with the following rhyme scheme: AABBA: AAB + refrain, + refrain; AABBA + C.

Austin Dobson wrote many rondeaus to this exacting plan, including the ingenious "You bid me try":

"You bid me try, Blue-Eyes, to write
A Rondeau. What!—forthwith?—to-night?
Reflect. Some skill I have, 'tis true:—
But thirteen lines!—and rhymed on two!
"Refrain", as well. Ah, hapless plight!

Still, there are five lines,—ranged aright.
These Gallic bonds, I feared, would fright
My easy Muse. They did, till you—
You bid me try!

That makes them eight. The port's in sight:—
'Tis all because your eyes are bright!
Now just a pair to end in 'oo'—
When maids command, what can't we do.
Behold!—the RONDEAU, tasteful, light,
You bid me try!"

The Roundel.

The roundel is a variation of the rondeau. Swinburne in his "Century of Roundels" wrote a hundred, and his pattern is usually followed. It consists of nine full lines, plus the refrain (consisting of the opening half of the first line), which is twice repeated, giving eleven lines all told. Only two rhymes are used throughout. The roundel is divided into three stanzas with the following rhyme scheme: ABA + refrain B; BAB; ABA + refrain B.

A Roundel by Swinburne.

The Roundel.

"A Roundel is wrought as a ring or a starbright sphere,
With craft of delight and with cunning of sound unsought
That the heart of the hearer may smile if to please his ear
A roundel is wrought.

Its jewel of music is carven of all or of aught—
Love, laughter, or mourning – rememberance of rapture of fear—
The fancy may fashion to hand in the ear of thought.

As a bird's quick song runs round, and the hearts in us hear—
Pause answers to pause, and again the same strain caught,
So moves the device whence, round as a pearl or tear,
A roundel is wrought."

The Rondel.

The rondel is a form of verse similar to the rondeau. The modern English version consists of fourteen lines all told. Only two rhymes are used, and the initial two lines are repeated as lines 7 and 8 and again as lines 13 and 14. The rondel is frequently arranged in three stanzas with a rhyme scheme as follows: ABBA; ABAB; ABBAAB.

The rondel was revived in the nineteenth century by Bridges, Dobson, Gosse, and Henley, and Dobson's "Love comes back to his vacant dwelling" is one of the best known.

The Ballade.

There are several kinds of ballade, but the most popular modern form consists of three eight-lined stanzas followed by an envoy of four lines. Each of the stanzas and the envoy end with a refrain. The rhymes of the eight-lined stanzas are ABABBCBC and of the envoy BCBC.

Austin Dobson wrote several ballades of this kind, the best known being, "This was the Pompadour's fan", and "And where are the galleons of Spain?"

Chaucer's "Balade", "Hyd, Absolon, thy gilte tresses clere," is of an earlier seven-lined type without an envoy.

A ballade by Austin Dobson:

The Ballad of the Thrush.

"Across the noisy street
I hear him careless throw
One warning utterance sweet:
This faint at first, and low
The full notes closer grow:
Hark! What a torrent gush!
They pour, they overflow—
Sing on, sing on, O Thrush!

What trick, what dream's deceit
Has fooled his fancy so
To scorn of dust and heat?
I, prisoned here below,
Feel the fresh breezes blow,
And see, thro' flag and rush,
Cool water sliding slow—
Sing on, sing on, O Thrush!

Sing on. What though thou beat
On that dull bar thy foe!
Somewhere the green boughs meet
Beyond the roofs a-row:
Somewhere the blue skies show,
Somewhere no black walls crush
Poor hearts with hopeless woe—
Sing on, sing on, O Thrush!

Envoy.
Bird, though they come we know,
The empty cage, the hush;
Still, ere the brief day go
Sing on, sing on, O Thrush!"

The Chant Royal.

The chant royal is a longer form of ballade. It has five stanzas of eleven lines and an envoy of five lines.

The rhyme scheme is ABABCCDDEDE, and the envoy has rhyme DDEDE.

The Sestina.

The sestina has six stanzas, each of six lines. The end words to the lines of the first stanza are repeated as end words in the other five stanzas, but in a different and stereotyped order. The poem concludes with an envoy.

The first sestina published in English was in Spenser's "Shepheardes Calender" (1579). Swinburne wrote many, including "I saw my soul at rest upon a day".

Metrical Forms of Japanese Origin.

The Haiku.

A poem of three syllabic lines, unrhymed. The first and third lines are of five syllables, the middle one has seven. It creates a vivid pictorial image expressing an imaginative or spiritual insight. The following gives some idea of the form:

Morning's white light, a
new beginning heralded
by a plump black bird.

As Japanese is a language without stresses its poetic forms are impossible to reproduce exactly in English. Most poets therefore concentrate on trying to capture the quality and spirit of the form rather than its exact structure. Pound's "Fan Piece for her Imperial Lord" is an example:

"O fan of white silk,
clear as frost on the grass-blade,
You also are laid aside."

The Tanka.

A poem similar in kind to the Haiku contains five lines. The first and third contain five syllables each, the remainder seven.

VI. CONCLUSION.

The foregoing account is no more than a description of our verse forms. It in no way implies that verse is written according to rules.

We have only to look at Shakespeare's lyrics [OBEV 117–133] to realise how brilliantly free and inventive the poet can be in devising new and delightful patterns of verse—many of them so subtle as to be very difficult to define. All that the students and critics can do is to follow in the poet's wake, endeavouring to understand and elucidate the forms that the maker has created.

V. FIGURES OF SPEECH

We constantly use figurative language without realising it. When we say that we are "browned off", "fed up", "at the end of our tether", we do not expect to be taken literally. We are in fact employing metaphors.

An understanding of metaphors and other figurative expressions enables us to use our language with greater confidence and effectiveness. It also helps us to understand more fully what others have written. Especially is it valuable when we read a good novel, play, or poem, for to the creative writer figurative language is as natural as the air he breathes.

The following guide to our figures of speech is arranged alphabetically for ease of reference.

Alliteration. A kind of repetition. Two or more words in close succession beginning with the same letter, or sound, usually a consonant. Up to the fourteenth century much English verse was written according to an alliterative principle, as in this modernised quotation from "Piers Plowman":

"I had *w*andered me *w*eary so *w*eary I rested me
On a *b*road *b*ank by a *m*erry-sounding *b*urn."

A strong tendency to alliteration still survives n our poetry. Shakespeare ridicules it in the mechanical's play in "A Midsummer Night's Dream" (Act V, Scene 1) in such lines as—

"Whereat, with blade, with bloody blameful blade,
He bravely broach'd his boiling bloody breast."

Anti-climax. See Bathos.

Antithesis. A figure of speech where ideas are so set out that they are in sharp contrast to each other, *e.g.*,

"Better to reign in hell, than serve in heav'n."
Milton.

"To err is human to forgive, divine."
Pope.

Apostrophe. A figure of speech where the speaker or writer suddenly breaks off and directly addresses some other person who may be present either in the flesh or only in the imagination. Often it is not a person but a thing, abstraction, or personification that is addressed, as in Milton's famous apostrophe, "Hail, holy light" in "Paradise Lost" Book III, line 1. Apostrophe can be used with comic effect, *e.g.*,

"She turns, O guardian angels stop her
From doing anything improper."

(This couplet is also, incidentally, an example of bathos.)

Assonance. (1) Assonance is correspondence of vowel sounds. For instance, in the opening lines of the "fairy song" in "A Midsummer Night's Dream" (Act II, Scene 2) there is a play on only three vowels, and this repetition helps towards the effect of a magic charm, *e.g.*,

"Philomel with melody, Sing"

In Tennyson's poem "Break, break, break" the repetition of the "o" sound in the second line is like an outcry of grief, *e.g.*,

"On thy cold grey stones, *O* Sea!"

(2) Assonance is sometimes used instead of rhyme, especially in early folk poetry. Here there is correspondence of one word with another in the accented vowel and any vowels which follow, but not in the consonants, *e.g.*, in "King Estmere", "Spain" is rhymed with "same" and "barone" with "home.".

Bathos or Anti-climax. A figure of speech that consists of a sudden and ludicrous descent from lofty to trivial things. In "The Rape of the Lock" Pope wittily used bathos to satirise the frivolity of the woman of fashion, who lacking all sense of proper feeling, casts the same "screams of horror", and "shrieks to pitying heav'n".

"When *husbands*, or when *lapdogs* breathe their last."

The careless writer may fall to bathos which is unintentionally comic in its effect. The word "bathos" in Greek means "depth".

Climax. A figure of speech where ideas are set out in such a way that each rises above its predecessor in scale. In Greek the word "climax" means a ladder. One of the finest examples is in Shakespeare's "The Tempest" (Act IV, Scene 1) when Prospero says,

"And, like the baseless fabric of this vision,
The cloud-capp'd towers, the gorgeous palaces,
The solemn temples, the great globe itself,
Yea, all which it inherit, shall dissolve."

Epigram. A concise and pointed saying, effective by its wit and ingenuity. It often uses antithesis. S. T. Coleridge's definition of this form is in itself an epigram, *e.g.*,

"What is an epigram? a dwarfish whole:
Its body brevity, and wit its soul."

Euphemism. A figure of speech where a harsh or distressing expression is replaced by one that is gentler, if less accurate. Thus we may call a lie a "flight of fancy", or a "terminological inexactitude". There is a striking instance of euphemism in "Macbeth" (Act I, Scene 5), when Lady Macbeth, planning the murder of her guest, Duncan, says, "He that's coming must be provided for."

Hypallage or "Transferred Epithet." A figure of speech where an adjective, or adverb, is separated from the word to which it belongs grammatically, and is transferred to some other word in the sentence, its unusual position giving it a kind of emphasis. The word "obsequious" is thus transferred in the sentence "A lacquey presented an obsequious cup of coffee".

Hyperbole. A figure of speech where there is a deliberate use of exaggeration for the sake of effect as in the phrase "tons of money". Lady Macbeth uses hyperbole when she says, "Here's the smell of blood still; all the perfumes of Arabia will not sweeten this little hand" (Act V, Scene 1).

Writers of advertisements, blurbs and film trailers frequently indulge in hyperbole.

Innuendo. A figure of speech where something is hinted at, or suggested, but not openly stated. Dickens uses innuendo to suggest Scrooge's stinginess by saying, "Darkness was cheap, and Scrooge liked it".

Irony. (1) A figure of speech where the speaker says one thing but intends the opposite to be understood. Shylock uses the word "courtesies" ironically when he says,

"Fair sir, you spit on me on Wednesday last;
You spurn'd me such a day; another time
You call'd me dog: and for these courtesies
I'll lend you thus much moneys."
"Merchant of Venice" (Act I, Scene 3).

The use of irony can clearly be seen in Shakespeare's "Julius Cæsar" in Antony's well-known speech to the citizens. They gradually realise that when Antony repeats that Brutus and the rest are "honourable men", he is speaking ironically, and intends the opposite. When they fully perceive this they cry, "They were traitors . . . villains, murderers". ("Julius Cæsar," Act III, Scene 2.)

(2) *Dramatic irony* is the use of words which have a second inner significance that is not realised by some of the actors in a scene. For instance, in Sheridan's "School for Scandal," Act IV, Scene 3, Sir Peter admires Joseph Surface's useful screen, and Surface replies, "Oh yes, I find great use in that screen." He and the audience know, but Sir Peter does not, that at that very moment the screen is concealing Sir Peter's own wife who had rashly visited Joseph.

It is helpful to remember that in Greek the word "irony" means "dissimulation."

Litotes. A figure of speech which is really a special kind of understatement (or Meiosis). Instead of making a positive statement (*e.g.*, "This is a difficult task") we might use Litotes, and say "This is no easy task", thus expressing a positive by the negative of its opposite.

Malapropism. An amusing inaccuracy in vocabulary. Words that have an accidental similarity in sound may become confused in the speaker's mind and the wrong word may come uppermost. Thus Mrs. Malaprop complains that the disobedience of her niece gives her, not "hysterics", but "hydrostatics." It is not surprising that Mrs. Malaprop, of Sheridan's "The Rivals", has given her name to this kind of verbal confusion, though many before her time, including humble folk in Shakespeare's plays, have uttered malapropism. Bottom, in "A Midsummer Night's Dream," says that in the wood they "may rehearse more obscenely" when he means "obscurely".

Meiosis. A figure of speech where a deliberate understatement is made for the sake of effect. English people are especially fond of Meiosis and often use it colloquially, in such an expression as "He made a very 'decent' contribution", meaning a very "generous" contribution. The full meaning of what we intend is often conveyed by the tone of voice, *e.g.*,

"This is *some* war."

Metaphor. It is helpful to think of the figure of speech, metaphor, as a condensed simile. In metaphor one thing is not merely *compared* to another, as in simile but is boldly spoken of as if it actually *were* that other. Thus Bacon, in the following metaphor, does not say books are *like* food, but speaks of them as if they actually *were* food, *e.g.*, "Some books are to be tasted, others to be swallowed, and some few to be chewed and digested."

Metaphor is usually defined as the transfer of a name, or descriptive term, to some object to which it is not properly applicable, thus making an implicit comparison. Shakespeare uses nautical terms to describe our human situation when Brutus says,

"There is a tide in the affairs of men which, taken at the flood, leads on to fortune" ("Julius Cæsar," Act IV, Scene 3).

In *Mixed Metaphor* two or more inconsistent metaphors are used of the same object, as when, speaking of a suspicion, someone said, "I smell a rat; I see it in the air; but I will nip it in the bud."

Metonymy. A figure of speech where a person or thing is not named directly, but by some associated thing. Instead of saying, "The prisoner addressed the magistrate", we might use metonymy and say, "The prisoner addressed the bench". Similarly, "a speech from the Lord Chancellor" is sometimes called "a speech from the Woolsack".

Onomatopœia. The use of words which imitate or echo the sounds they suggest. *e.g.*,

"Seas half-frozen slushed the deck with slime."
Masefield.

Oxymoron. A figure of speech where words that are usually contradictory are combined in one expression, *e.g.*, "bitter-sweet".

"I know this is a joyful trouble to you."
"Macbeth", Act II, Scene 3.

Paradox. A figure of speech where a statement is made that at first sight seems contradictory or absurd, *e.g.*,

"The rule of the road is a paradox quite:
If you keep to the left, you are sure to be right".

and

"The Child is father of the Man;"
Wordsworth.

Pathetic Fallacy. A figure of speech where it is assumed that things of nature have feelings like those of human beings, *e.g.*,

"And daffadillies fill their cups with tears".
Milton.

In Greek "pathos" means "feeling".

Personification. A figure of speech where some abstraction, or some inanimate thing is represented as a person, *e.g.*,

"Rule, Britannia".
James Thomson.

"But look the dawn in russet mantle clad
Walks o'er the dew of yon high eastern hill."
Hamlet, Act I, Scene 1.

Personification is really a special kind of metaphor.

Pun. The use of words so as to convey a double meaning, as in Belloc's couplet

"When I am dead, I hope it may be said:
'His sins were scarlet, but his books were read'".

In the three puns that follow there is a suggestion of a banking transaction! "The Egyptians received a check on the bank of the Red Sea which was crossed by Moses." Puns, which were popular in the nineteenth century especially with Lamb and Hood, are now out of favour.

Simile. A figure of speech which makes a comparison pointing out a similarity between things otherwise unlike. It is usually introduced by "like" or "as", *e.g.*,

"Men fear death as children fear to go in the dark."
Bacon.

"His own thought drove him like a goad."
Tennyson.

Spoonerism. An accidental transposition of the sound of two words, so called after Rev. W. A. Spooner, warden of New College, Oxford, *e.g.*,

"You have hissed all my mystery lectures" for "You have missed all my history lectures".

Synecdoche. A figure of speech where the name of a part is used for the whole, or the whole for the part, *e.g.*,

"A fleet of a hundred sail",

meaning of a hundred ships.

Synecdoche is really a special kind of Metonymy.

Transferred Epithet. See Hypallage.

VI. LITERARY FORMS

Allegory. A description or story which has a second and deeper significance below the surface. The characters are really personifications, usually representing some vice or virtue. Allegory flourished in the Middle Ages, but the best-known allegory in the world is Bunyan's "Pilgrim's Progress" (1678), which has been translated into over a hundred different languages and dialects. On the surface "The Pilgrim's Progress" is the story of a journey in which the hero encounters many difficulties but at last reaches his destination. Its inner meaning is the progress of the Christian soul through life on earth. Spenser's "Faerie Queene" (1589 and 1596) is a more subtle and complex allegory, capable of several interpretations, religious, ethical, and political. Allegory has been described as extended metaphor. *See* M68.

Autobiography. The story of a man's (or woman's) own life, written by himself. The autobiography is becoming increasingly popular, recent excellent examples being Stephen Spender's *World within World*, Richard Church's *Over the Bridge* and Laurie Lee's *Cider with Rosie*.

Ballad. There are two chief types of ballad:

1. A light song, often sentimental, as was the Victorian ballad, or a popular song, often of a personal kind, praising or attacking some notability.

2. A traditional poem, passed on by word of mouth. Many of our traditional ballads date from the 15th century. They tell some stirring tale, as do the many ballads about Robin Hood. Sometimes they record an actual occurrence, like the ballad "The Battle of Otterbourne", which tells of a Border skirmish, fought in 1388. Such ballads are enlivened by lively dialogue, and they use a special kind of stanza, which is described on M63.

Ballade. A short highly stylised poem, with a strict verse form. *See* M66.

Biography. A narrative telling the life story of some actual person, usually a well-known figure. The most famous biographer of classical times was Plutarch, who in the 1st century A.D. wrote his series of parallel "Lives" of twenty-three Greeks and twenty-three Romans. The English translation of this provided Shakespeare with some of the plots of his plays. Boswell's *Life of Samuel Johnson* (1791) is our best-known English biography.

Burlesque. The aim of burlesque is to make us laugh by ridiculing the work of some other writer. Sometimes it treats his serious subject in a mocking way. Sometimes it takes the form of an absurd imitation or caricature of his style. Some of our most successful burlesques are dramatic in form, like Sheridan's "The Critic", produced in 1779. This has a play within a play, called "A Tragedy Rehears'd", a brilliant burlesque of the sentimental, historical plays so popular in his time.

Chant Royal. A poem of a strictly formal kind, French in origin. *See* M66.

Clerihew. A single-stanza verse form, four lines long. *See* M65.

Comedy. A play which is happy and amusing in tone, but not necessarily light or superficial. A comedy always has a fortunate conclusion. Shakespeare's "Twelfth Night" and Oscar Wilde's "The Importance of being Earnest" are typical examples

Drama. A play in verse or prose, where the story is unfolded and the characters represented through the actions and speeches of actors on a stage. It is essential to good drama that there should be some kind of dynamic action and some conflict between the characters. In comedy the conflict is usually open and external. "As You Like It" for instance, begins with a quarrel between Orlando and Oliver. But most of the world's finest tragedies reveal also an inner conflict in the soul of man. In "Hamlet" the hero is at odds with many people, including his mother, the king, Ophelia, Polonius, and Laertes, but all these struggles are of secondary significance, compared with the conflict in his own mind. Even a play like "Waiting for Godot", which reduces incident and conflict to a minimum, must make some concession to the demand of the audience for the dynamic. Drama cannot be static. Occasionally poets have written dramas which they knew were not practicable for the stage. Shelley's lyrical dramas, "Prometheus Unbound" and "Hellas", are of this kind. *See* Section I.

Eclogue. In classical literature a brief poem, usually in the form of a dialogue between shepherds. It was a popular form in the time of the Renaissance; Spenser's "Shepheardes Calendar" (1579) consists of twelve eclogues, one for each month of the year.

Elegy. A lyric poem of lamentation for the dead. Gray's "Elegy in a Country Churchyard" (1750) is the best-known English elegy. It reflects in a general way on the "destiny obscure" of the humble folk who are buried in a quiet churchyard, probably that of Stoke Poges, but most elegies mourn the death of only one person. Such are Shelley's "Adonais" (1821), on the death of Keats, and Matthew Arnold's "Thyrsis" (1867), commemorating his friend Arthur Hugh Clough. Tennyson's "In Memoriam" (1850) is unusual, in that it is not a single elegy, but a series of elegiac poems, inspired by the poet's grief for the death in 1833 of his friend Arthur Hallam.

Epic. A very long narrative poem, usually consisting of several books. The epic tells of the splendid deeds of some hero of history or legend and is frequently concerned with war. Some of the world's greatest epics are the Greek "Iliad" and "Odyssey", ascribed to Homer, the Latin "Aeneid" of Virgil, the Hindu "Mahabharata", and Milton's "Paradise Lost", whose hero is God himself. The epic is distinguished by its sustained dignity of style.

Epilogue. *See* Prologue.

Essay. The word essay, derived from the French, means literally an "attempt" or "endeavour", and as a literary term it applies to a short prose composition which attempts to present the author's reflections on any subject he chooses. As a literary form the essay derives from the French "Essais" of Montaigne, first translated into English by Florio in 1603. Our first English essayist was Francis Bacon, who published between 1597 and 1625 three volumes of his essays, brief, pithy, and objective in character. In course of time the essay has become more subjective and personal, especially in the hands of Lamb, Hazlitt, and contemporary writers.

Extravaganza. A composition, musical or literary, which uses improbable and fantastic elements and incidents. A good example of narrative extravaganza is Thackeray's *Rose and the Ring* (1855), in which, for instance, Gruffanuff's husband, the footman, is, because of his rudeness, turned into a door-knocker. Extravaganzas are frequently dramatic in form, and most pantomimes may be regarded as such.

Fable. A very brief story designed to teach some lesson or moral. The characters of the story are often animals, birds, or insects, which converse like human beings. The most famous of all fables are those attributed to Aesop, and those of La Fontaine, the French writer of the 17th century.

Farce. A species of dramatic comedy whose whole aim is to excite laughter. It does not scruple to use improbable characters and incidents and absurd situations. "Charley's Aunt" is a typical farce.

Lampoon. A coarse satire (*q.v.*) attacking an individual. Lampoons are usually short. The word itself is derived from a French word meaning "drinking song."

Limerick. A single-stanza verse form, 5 lines long and with a formal metre and rhyme scheme. *See* M64.

Lyric. In ancient Greece a lyric was originally a poem meant to be sung to the accompaniment of the lyre, a stringed musical instrument rather like a small harp. Later the word was used for a poem with song-like qualities: short, usually divided into verses, and expressing the feelings of the poet. The lyric flourished in England in the Elizabethan age, as witnessed by the lovely lyrics scattered through Shakespeare's plays. Neglected in the 18th century, it became popular again with the Romantic poets of the 19th century. Odes, elegies, and sonnets are all species of lyrics.

Mask or Masque. A dramatic entertainment performed by amateurs and originating in the court masquerade. The action or plot of the masque is of the slightest and there is little concern with portrayal of character, for the masque gives pleasure by means of its verse, music, and dancing, and its elegant costume and scenery. It was very popular in the 16th and 17th centuries, and from 1605 Ben Jonson wrote many court masques, for which Inigo Jones designed original costumes and settings. Our best-known examples are Shakespeare's masque in Act IV of "The Tempest" and Milton's "Comus".

Melodrama. There are two meanings of the word melodrama.

1. In the early 19th century a melodrama meant a play, usually of a romantic and sensational kind, in which songs were inserted, and where an orchestra accompanied the action. The musical comedy of today might be regarded as its modern counterpart.

2. Today the word melodrama is used of an inferior kind of play, which deliberately excites the emotions by its sensational and violent happenings, but which has a happy ending. We should be careful to distinguish melodrama, which uses violence for its own sake, from serious plays, like "Hamlet" or "King Lear", where violent acts are only incidents necessary to a profound interpretation of human conduct.

Memoirs. The word is normally used of a record of events of which the author has some personal experience or special source of information.

Miracle Plays. Mediæval verse plays produced from the late 14th to 16th centuries by the town guilds and performed in the market-place, or other suitable open space. They consisted of a series of dramatised stories from the Bible or Lives of Saints. Each scene would be allotted to one of the guilds, which was then responsible for its production on a wheeled stage. As soon as the actors of one guild had completed their scene, their stage would be trundled off, sometimes to another rendezvous, and would itself be succeeded by another stage with its scene, until a whole cycle of episodes had been performed. Four great cycles of miracle plays are still extant, called after the towns where they were probably performed, York, Coventry, Chester, and Wakefield. The Wakefield cycle is often called the Towneley cycle. The plays have not only a strong religious sense but also a lively comic spirit. The Towneley cycle has some especially racy comic scenes. One popular incident shows the noisy quarrel that results when Noah's wife refuses to go into the ark.

Mock Heroic. A species of parody (*q.v.*), caricaturing some play or poem written in a lofty and high-flown style. "The Rehearsal" (1672) by Villiers, is typical. It is an absurd imitation ridiculing the artificial and high falutin' heroic plays which were then in vogue.

Monody. In Greek literature an ode sung by a single voice, like our solo in music. In English literature it signifies a poem of mourning for someone's death. The elegies "Lycidas", by Milton, and "Thyrsis", by Matthew Arnold, were both called monodies by their authors.

Monologue. Originally a scene where one person of the drama spoke alone. Today it usually means a dramatic composition for a single actor, such as the well-known Lancashire monologues presented by Stanley Holloway. The word is also sometimes used as meaning soliloquy.

Moralities or Morality Plays. Mediæval verse plays of an allegorical kind, which attempted to teach lessons of virtue, the persons of the drama usually being not real people, but personifications. Most Moralities date from the 15th century, the best known being "Everyman", which is Dutch in origin. The hero, Everyman, is summoned by Death, and vainly appeals for help to his friends, Fellowship, Kindred, Goods, Knowledge, Beauty, and Strength, but all fail him. Only his own

Good Deeds will consent to accompany him on his last journey.

Mysteries or Mystery Plays. Some modern writers use the term "Mystery play" instead of "Miracle play" (*q.v.*). It is really an alternative title. One critic tried to distinguish between "Mystery plays", as concerned with stories from the Gospels, and "Miracle plays", as concerned with the lives and deeds of Saints, but this distinction is not usually followed.

Novel. A lengthy prose fiction. It is traditionally a realistic story of people and events, but in the present century many novelists have sought rather to express the fluctuating patterns of the inner life of the mind, while the chief interest of the French "new novelists" is language itself.

Some consider Thomas Nashe's picaresque romance *The Unfortunate Traveller* (1594) to be the first English novel but Samuel Richardson is more usually thought to have invented this literary form. His *Pamela* (1740–41), the first realistic novel in English, won a European reputation. *See also* M4–40.

Ode. In classical literature an ode was a poem to be sung. In English literature it signifies a lyric poem, usually in rhyme, and is seldom longer than 150 lines. It is usually in the form of an address, and lofty in its feeling and style. The ode was popular with the romantic poets. Some of our best known are Shelley's "Ode to the West Wind", and Keats' "Ode to a Nightingale", "Ode on a Grecian Urn", and "To Autumn", all of them published in 1820.

Parable. A parable is an arresting simile or metaphor from nature or common life, which may be elaborated into a life-like story. It presents a situation which at a certain point implies some correspondence with ethical or religious principle. *See* C. H. Dodd's *The Parables of the Kingdom.*

Parody. A literary caricature, which mimics the themes and style of some other author in such a way as to make his faults seem absurd and laughable. J. C. Squire's *Tricks of the Trade* is an amusing collection of his skilful parodies of such writers as Byron, Wordsworth, and Masefield.

Pastoral. A pastoral poem, romance, or play is one in which the life of shepherds or of simple rustic folk is portrayed in an idealised way. Originating in Greek literature, the pastoral was revived at the time of the Renaissance. Spenser's "Shepheardes Calendar" consists of twelve pastoral eclogues. Shakespeare's "As You Like It" is a pastoral play, Milton's "Lycidas" is a pastoral elegy and his "Comus" a pastoral masque. There is usually in the pastoral a deeper meaning below the surface. A critic has said, "The shepherd's cloak was the acknowledged disguise of the lover, the poet, the courtier, the pastor of souls, the critic of contemporary life." In the pastoral form the charm of a simple setting and deeper significance are combined.

Prologue and Epilogue. Generally speaking, a prologue means a foreword, or preface, and an epilogue an appendix to a literary work, but the terms are often used more specifically when referring to a play. Here the prologue is a short speech in verse or prose spoken to the audience by one of the actors before the play begins, the epilogue a similar speech after its conclusion. The prologue endeavours to put the audience into a receptive state of mind, the epilogue to ask for a kind reception to the play. Shakespeare's "Romeo and Juliet" has a prologue, his "As You Like It" an epilogue, spoken by Rosalind, who says, "Good plays prove the better by the help of a good epilogue." In the 18th century it was customary for a leading actor to speak the prologue and for a leading actress to make a plea for the play in the epilogue.

Romance. The romance of the early Middle Ages was a fictitious tale in verse, telling the adventures of some hero of chivalry, the interest being in the incidents, sometimes of a supernatural kind, rather than in character. The most famous of these early romances is the French "Chanson de Roland" of the early 12th century. In the later Middle Ages a romance might be written in prose. In the 16th and 17th centuries a romance meant a tale in either prose or verse in which the scenes and incidents were remote from those of real life. Sir Philip Sidney's "Arcadia" (1590), written to entertain his sister, is of this type. Today the word romance is rather vaguely used of a tale of somewhat improbable events. Sir Henry Rider Haggard wrote several such romances, including *King Solomon's Mines* (1886) and *She* (1887).

Rondeau. A poem of a strictly formal kind, French in origin. *See* M65.

Rondel. A poem similar in form to the rondeau. *See* M66.

Roundel. A variation of the Rondeau. *See* M65.

Saga. The word saga, which is of Norse origin and means story, is applied to the mediæval prose narratives of Iceland and Norway, especially those concerned with the traditions of Icelandic families and Norwegian kings. William Morris, in his "Earthly Paradise", gives in "The Lovers of Gudrun" a version of the Icelandic Laxdæla Saga.

Satire. A work in either verse or prose attacking folly and vice. Pope's "Dunciad", in verse-published between 1728 and 1743, ridicules contemporary authors and literary follies in a massive attack on dullness and literary hacks. Swift's *Gulliver's Travels* (1726), which on the surface is a series of prose tales of travel to imaginary countries, is actually a comprehensive satire. It begins, in the first book on "Lilliput", with incisive ridicule of the squabbles between English political parties and religious sects, and culminates, in the final book on the Houyhnhnms, in a devastating attack on all that is bestial in human nature. Samuel Butler's *Erewhon* (an anagram of Nowhere), published in 1872, also uses a prose travel tale in his satirical exposure of Victorian convention and hypocrisy. Although not precisely satires, many of Shaw's plays are satirical in spirit. "Arms and the Man" may be considered in one of its aspects as a satire on war.

Sestina. A poem of a strictly formal kind, French in origin. *See* M66.

Skit. A light satire, often in the form of parody.

Soliloquy. In a soliloquy a man talks to himself, or utters his thoughts aloud regardless of the presence of others who may hear him. The word is usually applied to such utterances by a character in a play. The most famous soliloquies in literature are those of Hamlet.

Sonnet. A lyric poem of fourteen lines, with an intricate rhyme scheme. *See* M64.

Squib. A brief, sharp satire (*q.v.*) attacking an individual.

Threnody. A term from the Greek, seldom used today. It means a song of mourning, especially a lament for the dead.

Tragedy. A play, or other literary work, which is preoccupied with the serious and unhappy aspects of life. It is sombre in tone and ends with misfortune. Shakespeare's "Macbeth" and Ibsen's "Ghosts" are typical tragedies.

Tragi-Comedy. The word is used in two different ways:

(*a*) It may denote a play (or very occasionally a story) which combines both tragic and comic elements. Chekhov's "The Cherry Orchard" is a tragi-comedy of this type.

(*b*) It may also mean a play which is for the most part sombre in theme and tone, but which has a happy conclusion, like Shakespeare's "The Winter's Tale".

Trilogy. In Greek literature a series of three tragedies, like Aeschylus' trilogy, the "Oresteia," written when he was nearly seventy, in the 5th century B.C. In modern times the word trilogy is applied to any sequence of three literary works which are related to each other in subject and theme.

Triolet. A single-stanza verse form, eight lines long, and with a very formal pattern, French in origin. *See* M65.

Villanelle. A poem of a strictly formal kind, French in origin. *See* M65.

GENERAL COMPENDIUM

A collection of useful tables and data on a variety of unrelated subjects, including silver and china marks, SI units, weights and measures, phases of the moon, sunrise and sunset, eclipses, and abbreviations in common use.

TABLE OF CONTENTS

Abbreviations in Common Use	21–8

SCOTTISH MONARCHS

(1057–1603)

Monarch		Accession	Died
Malcolm III (Canmore)	Son of Duncan I	1058	1093
Donald Ban	Brother of Malcolm Canmore	1093	—
Duncan II	Son of Malcolm Canmore, by first marriage	1094	1094
Donald Ban	Restored	1094	1097
Edgar	Son of Malcolm Canmore, by second marriage	1097	1107
Alexander I	Son of Malcolm Canmore	1107	1124
David I	Son of Malcolm Canmore	1124	1153
Malcolm IV (the Maiden)	Son of Henry, eldest son of David I	1153	1165
William I (the Lion)	Brother of Malcolm the Maiden	1165	1214
Alexander II	Son of William the Lion	1214	1249
Alexander III	Son of Alexander II, by second marriage	1249	1286
Margaret, Maid of Norway	Daughter of Eric II of Norway, granddaughter of Alexander III	1286	1290
John Baliol	Grandson of eldest daughter of David, Earl of Huntingdon, brother of William the Lion	1292	1296
Robert I (Bruce)	Great-grandson of 2nd daughter of David, Earl of Huntingdon, brother of William the Lion	1306	1329
David II	Son of Robert I, by second marriage	1329	1371
Robert II (Stewart)	Son of Marjorie, daughter of Robert I by first marriage, and Walter the Steward	1371	1390
Robert III	(John, Earl of Carrick) son of Robert II	1390	1406
James I	Son of Robert III	1406	1437
James II	Son of James I	1437	1460
James III	Eldest son of James II	1460	1488
James IV	Eldest son of James III	1488	1513
James V	Son of James IV	1513	1542
Mary	Daughter of James V, by second marriage	1542	1587
James VI (ascended the Throne of England 1603)	Son of Mary, by second marriage	1567	1625

BRITISH PRIME MINISTERS

	Party	Served
George I, 1714–27		
George II, 1727–60		
Sir Robert Walpole	Whig	1721–42
Earl of Wilmington	Whig	1742–3
Henry Pelham	Whig	1743–54
Duke of Newcastle	Whig	1754–6
Duke of Devonshire	Whig	1756–7
Duke of Newcastle	Whig	1757–60
George III, 1760–1820		
Duke of Newcastle	Whig	1760–2
Earl of Bute	Tory	1762–3
George Grenville	Whig	1763–5
Marquis of Rockingham	Whig	1766
Duke of Grafton	Whig	1766–9
Lord North	Tory	1770–82
Marquis of Rockingham	Whig	1782
Earl of Shelburne	Whig	1782–3
Duke of Portland	Coalition	1783
William Pitt	Tory	1783–1801
Viscount Sidmouth	Tory	1801–4
William Pitt	Tory	1804–6
Lord Grenville	Whig	1806–7
Duke of Portland	Tory	1807–9
Spencer Perceval (assassinated)	Tory	1809–12
George IV, 1820–30		
Earl of Liverpool	Tory	1812–27
George Canning	Tory	1827
Viscount Goderich	Tory	1827
Duke of Wellington	Tory	1827–30
William IV, 1830–7		
Earl Grey	Whig	1830–4
Viscount Melbourne	Whig	1834
Sir Robert Peel	Tory	1834–5
Viscount Melbourne	Whig	1835–7
Victoria, 1837–1901		
Viscount Melbourne	Whig	1837–41
Sir Robert Peel	Tory	1841–6
Lord John Russell	Whig	1846–52
Earl of Derby	Tory	1852
Earl of Aberdeen	Peelite	1852–5
Viscount Palmerston	Liberal	1855–8
Earl of Derby	Tory	1858–9
Viscount Palmerston	Liberal	1859–65
Earl Russell	Liberal	1865–6
Earl of Derby	Conservative	1866–8
B. Disraeli	Conservative	1868
W. E. Gladstone	Liberal	1868–74
B. Disraeli	Conservative	1874–80
W. E. Gladstone	Liberal	1880–5
Marquis of Salisbury	Conservative	1885–6
W. E. Gladstone	Liberal	1886
Marquis of Salisbury	Conservative	1886–92
W. E. Gladstone	Liberal	1892–4
Earl of Rosebery	Liberal	1894–5
Marquis of Salisbury	Conservative	1895–1901
Edward VII, 1901–10		
Marquis of Salisbury	Conservative	1901–2
A. J. Balfour	Conservative	1902–5
Sir H. Campbell-Bannerman	Liberal	1905–8
H. H. Asquith	Liberal	1908–10
George V, 1910–36		
H. H. Asquith	Liberal	1910–15
H. H. Asquith	Coalition	1915–16
D. Lloyd George	Coalition	1916–22
A. Bonar Law	Conservative	1922–3
S. Baldwin	Conservative	1923–4

S. Baldwin	Conservative	1924–9
J. R. MacDonald	Labour	1929–31
J. R. MacDonald	National	1931–5
S. Baldwin	National	1935–6
Edward VIII, 1936		
George VI, 1936–52		
S. Baldwin	National	1936–7
N. Chamberlain	National	1937–39
N. Chamberlain	War Cabinet	1939
W. S. Churchill	War Cabinet	1940–45
W. S. Churchill	Caretaker	1945
C. R. Attlee	Labour	1945–51
Sir W. S. Churchill	Conservative	1951–2
Elizabeth II, 1952–		
Sir W. S. Churchill	Conservative	1952–5
Sir A. Eden	Conservative	1955–7
H. Macmillan	Conservative	1957–63
Sir A. Douglas-Home	Conservative	1963–4
H. Wilson	Labour	1964–70
E. Heath	Conservative	1970–4
H. Wilson	Labour	1974–

PRESIDENTS OF THE UNITED STATES

The terms are for four years; only President F. D. Roosevelt has served more than two terms.

	Party	Served
1. George Washington	Fed.	1789–97
2. John Adams	Fed.	1797–1801
3. Thomas Jefferson	Rep.	1801–9
4. James Madison	Rep.	1809–17
5. James Monroe	Rep.	1817–25
6. John Quincey Adams	Rep.	1825–9
7. Andrew Jackson	Dem.	1829–37
8. Martin Van Buren	Dem.	1837–41
9. William H. Harrison (died in office)	Whig	1841
10. John Tyler	Whig	1841–5
11. James K. Polk	Dem.	1845–9
12. Zachary Taylor (died in office)	Whig	1849–50
13. Millard Fillmore	Whig	1850–3
14. Franklin Pierce	Dem.	1853–7
15. James Buchanan	Dem.	1857–61
16. Abraham Lincoln (assassinated)	Rep.	1861–5
17. Andrew Johnson	Rep.	1865–9
18. Ulysses S. Grant	Rep.	1869–77
19. Rutherford B. Hayes	Rep.	1877–81
20. James A. Garfield (assassinated)	Rep.	1881
21. Chester A. Arthur	Rep.	1881–5
22. Grover Cleveland	Dem.	1885–9
23. Benjamin Harrison	Rep.	1889–93
24. Grover Cleveland	Dem.	1893–7
25. William McKinley (assassinated)	Rep.	1897–1901
26. Theodore Roosevelt	Rep.	1901–9
27. William Howard Taft	Rep.	1909–13
28. Woodrow Wilson	Dem.	1913–21
29. Warren G. Harding (died in office)	Rep.	1921–3
30. Calvin Coolidge	Rep.	1923–9
31. Herbert C. Hoover	Rep.	1929–33
32. Franklin D. Roosevelt (died in office)	Dem.	1933–45
33. Harry S. Truman	Dem.	1945–53
34. Dwight D. Eisenhower	Rep.	1953–61
35. John F. Kennedy (assassinated)	Dem.	1961–3
36. Lyndon B. Johnson	Dem.	1963–69
37. Richard M. Nixon	Rep.	1969–

WEIGHTS AND MEASURES

Many kinds of measure now in use in the United Kingdom are gradually being converted from Imperial units to SI units. SI is short for "Système International d'Unités" and it is a system of metric units now coming into international use through the agency of such bodies as the General Conference of the International Bureau of Weights and Measures and the International Organisation for Standardisation (ISO) in whose work Britain participates. Information about SI units is available in booklets published by the British Standards Institution, Sales Branch, 101–113 Pentonville Road, London, N.1.

For a transitional period of some years, Imperial and SI units will be in use simultaneously. Important parts of the two systems are given separately below. A selection of useful conversion factors is on N8.

Unit Symbols Used in the Tables

Unit	Symbol	Unit	Symbol
metre	m	kilogramme	kg
yard	yd	gramme	g
foot	ft	pound	lb
inch	in	ounce	oz
mile	mile	hundredweight	cwt
square metre	m^2	poundal	pdl
square inch	in^2	pound-force	lbf
square mile	$mile^2$	foot pound-force	ft lbf
cubic metre	m^3	calorie	cal
cubic inch	in^3	British thermal unit	Btu
litre	l	horsepower	hp
gallon	gal	tonne	t

I. IMPERIAL WEIGHTS AND MEASURES

Length.

1 nail	= 2¼ in
1 link	= 7·92 in
12 in	= 1 ft
3 ft	= 1 yd
22 yd	= 1 chain
10 chains	= 1 furlong
8 furlongs	= 1 mile = 1760 yd = 5280 ft

Area.

144 in^2	= 1 ft^2
9 ft^2	= 1 yd^2 = 1296 in^2
484 yd^2	= 1 square chain
1210 yd^2	= 1 rood
4 roods	= 1 acre = 4840 yd^2
640 acres	= 1 $mile^2$

Volume.

1728 in^3	= 1 ft^3
27 ft^3	= 1 yd^3

Capacity.

4 gills	= 1 pint
2 pints	= 1 quart
4 quarts	= 1 gallon
2 gallons	= 1 peck
4 pecks	= 1 bushel
8 bushels	= 1 quarter
36 bushels	= 1 chaldron

The gallon, as the capacity standard, is based upon the pound.

1 gal = 277·274 in^3

Weight (Avoirdupois).

1 dram	= 27·343 75 grains
16 drams	= 1 oz = 437·5 grains
16 oz	= 1 lb = 7000 grains
14 lb	= 1 stone
28 lb	= 1 quarter
4 quarters	= 1 cwt = 112 lb
20 cwt	= 1 ton = 2240 lb

Troy Weight.

1 pennyweight	= 24 grains
480 grains	= 1 ounce

The only unit of troy weight which is legal for use in trade in Britain is the ounce Troy, and weighings of precious metal are made in multiples and decimals of this unit.

The term *carat* is not a unit of weight for precious metals, but is used to denote the quality of gold plate, etc., and is a figure indicating the number of 24ths of pure gold in the alloy, *e.g.*, a 9 carat gold ring consists of nine parts of pure gold and fifteen parts of base metals.

Nautical Measures.

1 nautical mile = 6080 ft = 1853·18 m
1 knot = 1 nautical mile per hour = 1·151 mile/h

Note.—In future the international nautical mile of 1852 m will be used.

Note.—The British Pharmaceutical Code and the British National Formulary—the official works of medicinal reference—no longer contain the apothecaries' units of measurement since medicine is now measured in metric units. Prescriptions are in 5 millilitre (ml) units; medicine bottles are in six sizes from 50 to 500 ml.

II. SI UNITS

There are six base SI Units. They are:

Quantity	*Name of Unit*	*Symbol*
length	metre	m
mass	kilogramme	kg
time	second	s
electric current	ampere	A
temperature	kelvin	K
luminous intensity	candela	cd

Derived units are normally stated in terms of the base unit. Examples: the SI units of velocity and density are, respectively, the metre per second (m/s) and the kilogramme per cubic metre (kg/m^3). Some important derived units have well-established names of their own. They are:

Quantity	*Name of SI unit*	*Symbol*	*Expressed in terms of SI base-units or derived units*
frequency	hertz	Hz	1 Hz = 1/s
force	newton	N	1 N = 1 kg m/s^2
work, energy, quantity of heat	joule	J	1 J = 1 N m
power	watt	W	1 W = 1 J/s
quantity of electricity	coulomb	C	1 C = 1 A s
electric potential, potential difference, tension, electromotive force	volt	V	1 V = 1 W/A
electric capacitance	farad	F	1 F = 1 A s/V
electric resistance	ohm	Ω	1 Ω = 1 V/A
flux of magnetic induction, magnetic flux	weber	Wb	1 Wb = 1 V s
magnetic flux density, magnetic induction	tesla	T	1 T = 1 Wb/m^2
inductance	henry	H	1 H = 1 V s/A
luminous flux	lumen	lm	1 lm = 1 cd sr
illumination	lux	lx	= 1 lx 1 lm/m^2

There are special prefixes for forming multiples and sub-multiples of the SI units. These are:

Factor by which the unit is multiplied	*Prefix*	*Symbol*
10^{12}	tera	T
10^{9}	giga	G
10^{6}	mega	M
10^{3}	kilo	k
10^{2}	hecto	h
10	deca	da
10^{-1}	deci	d
10^{-2}	centi	c
10^{-3}	milli	m
10^{-6}	micro	μ
10^{-9}	nano	n
10^{-12}	pico	p
10^{-15}	femto	f
10^{-18}	atto	a

Examples: one thousandth of a metre is one millimetre (1 mm); one million volts is one megavolt (1 MV). These prefixes are *recommended* but other multiples and sub-multiples will be used when convenient, *e.g.*, the centimetre (cm), the cubic decimetre (dm^3).

The following is a selection of special points to note:

(i) The name litre now means 1 cubic decimetre or 10^{-3}m^3 and is a measure of volume.

(ii) Days, hours, and minutes are still used to measure time, though some scientists may prefer to use kiloseconds, etc.

(iii) The SI unit of plane angle is the radian (rad), but degrees, minutes and seconds are still used as well. $1° = \frac{\pi}{180}$ rad; 1 rad = 57·295 78° = 57° 17′ 44·81″

(iv) A Celsius temperature, say 15 degrees, is written 15°C; note that 15C would mean 15 coulombs. *See* L21.

(v) The mole (mol) is important in science as a measure of "amount of substance" and may be adopted as a seventh basic SI unit. 1 mol is the amount of substance of a system which contains as many elementary units as there are carbon atoms in 0·012 kg of ^{12}C. The elementary unit must be specified and may be an atom, a molecule, an ion, an electron, etc., or a specified group of such particles. *See* F21(2).

(vi) The SI unit of area is the square metre (m^2) but the hectare (1 ha = 10^4m^2) will be the normal unit for land measure where we have previously used the acre. The are (a) = 10^2m^2.

(vii) The SI unit of pressure is the newton per square metre (N/m^2), but in some technical fields, notably meteorology, the unit of pressure is the bar which approximates to normal atmospheric pressure; 1 bar = 10^5 N/m^2.

II. SELECTED METRIC EQUIVALENTS FOR IMPERIAL WEIGHTS AND MEASURES

Length.

1 in	= 2·54 cm	= 0·0254 m
12 in = 1 ft	= 30·48 cm	= 0·3048 m
3 ft = 1 yd	= 0·9144 m	
1760 yd = 1 mile	= 1609·344 m	

Area.

1 in^2	= 6·4516 × 10^{-4} m^2	
144 in^2 = 1 ft^2	= 0·092 903 0 m^2	
9 ft^2 = 1 yd^2	= 0·836 127 m^2	
4840 yd^2 = 1 acre	= 0·404 68	
640 acres = 1 mile^2	= 2·589 99 × 10^6 m^2	

Volume.

1 in^3	= 1·638 71 × 10^{-5} m^3
1 ft^3	= 0·028 316 8 m^3
1 UK gal	= 0·004 546 092 m^3

Velocity.

1 ft/s = 0·3048 m/s
1 mile/h = 0·447 04 m/s = 1·6093 × 10^3 m/h

Capacity.

1 pint	= 0·568 *l* or 10^{-3} m^3	
2 pints = 1 quart	= 1·136 *l*	
4 quarts = 1 gal	= 4·546 *l*	
8 gal = 1 bushel	= 36·37 *l*	
8 bushels = 1 quarter	= 2·909 × 10^2	

Weight.

1 oz	= 28·35 g	
16 oz = 1 lb	= 0·453 592 37 kg	
14 lb = 1 st	= 6·350 kg	
112 lb = 1 cwt	= 50·80 kg	
20 cwt (2240 lb) = 1 long ton	= 1016 kg	
2000 lb = 1 short ton	= 907 kg	

Note.—1 tonne (t) = 1000 kg

Density.

1 lb/in^3	= 2·767 99 × 10^4 kg/m^3
1 lb/ft^3	= 16·0185 kg/m^3
1 lb/UK gal	= 99·7764 kg/m^3

Force.

1 pdl	= 0·138 255 N
1 lbf	= 4·448 22 N

Pressure.

1 lbf/in^2 = 6894·76 N/m^2

Energy (work, heat).

1 ft pdl	= 0·042 140 1 J
1 ft lbf	= 1·355 82 J
1 cal	= 4·1868 J
1 Btu	= 1055·06 J

Power.

1 hp = 745 700 W

Temperature.

1 Rankine degree = 1 Fahrenheit degree
= 5/9 Kelvin = 5/9 Celsius degree

(The Rankine scale of absolute temperature was developed from the Fahrenheit scale, exactly as the Kelvin scale was developed from the Celsius scale.)

Note.—Figures printed in **bold** type are exact. Unit symbols are the same in the singular and the plural and do not carry a full point (as a mark of an abbreviation).

INTERNATIONAL PAPER SIZES

Trimmed or finished sizes
"A" Series
(Books and Magazines)

Designation	Size	
	mm	in
A0	841 × 1189	33·11 × 46·81
A1	594 × 841	23·39 × 33·11
A2	420 × 594	16·54 × 23·39
A3	297 × 420	11·69 × 16·54
A4	210 × 297	8·27 × 11·69
A5	148 × 210	5·83 × 8·27
A6	105 × 148	4·13 × 5·83
A7	74 × 105	2·91 × 4·13
A8	52 × 74	2·05 × 2·91
A9	37 × 52	1·46 × 2·05
A10	26 × 37	1·02 × 1·46

Note.—The basis of the international series of paper sizes is a rectangle having an area of 1 sq. metre, the sides of which are in the proportion of 1 : $\sqrt{2}$ (a geometrical relationship, the side and diagonal of a square being in that proportion). In addition there is a series of "B" sizes intermediate between any two adjacent sizes of the "A" series (for posters, etc.) and of "C" sizes (for envelopes).

SIZES OF BOUND BOOKS

Name	Size of untrimmed page	
	in	mm
Foolscap octavo	6¾ × 4¼	170 × 110
Crown octavo	7½ × 5	190 × 125
Large crown octavo	8 × 5¼	205 × 135
Small demy octavo	8½ × 5⅝	215 × 145
Demy octavo	8¾ × 5⅝	220 × 145
Medium octavo	9 × 5¾	230 × 145
Small royal octavo	9¼ × 6⅛	235 × 155
Royal octavo	10 × 6¼	255 × 160

Note.—The standard for paperbacks is a trimmed page size of 7⅛ in × 4¼ in (180 mm × 110 mm).

25	77	− 40	− 40

To reduce Fahrenheit to Celsius (centigrade), subtract 32 degrees and multiply by 5/9; to reduce Celsius to Fahrenheit, multiply by 9/5 and add 32 degrees.

An alternative method, perhaps easier to remember, is to add 40 to the given figure, multiply by 5/9 (°F to °C) or 9/5 (°C to °F) and subtract 40.

BANK AND PUBLIC HOLIDAYS

In addition to Good Friday and Christmas Day, there are Bank holidays in most parts of England, Wales and the Channel Islands on New Year's Day, Easter Monday, in late Spring and late Summer (see below), and on the first weekday after Christmas (Boxing Day). The Channel Islands also observe Liberation Day, May 9. Scotland observes New Year's Day, Good Friday, a late Spring and a late Summer holiday (see below) and Christmas Day. In addition most towns in Scotland have locally determined holidays in the Spring and Autumn. Northern Ireland observes all the English holidays and, in addition, has a holiday on St. Patrick's Day, 17 March, and on 12 July, commemorating the Battle of the Boyne (1690). Easter Tuesday is also a customary holiday for industry and trade.

The Queen's birthday is observed in the Customs and certain other Government establishments as a holiday.

1974 Bank Holidays in England, Wales and Northern Ireland—Apr. 15, May 27, Aug. 26, Dec. 26
1975 —Jan. 1, Mar. 31, May 26, Aug. 25, Dec. 26

1974 Scotland—Jan. 1, Apr. 12, May 6, Aug. 5, Dec. 25
1975 —Jan. 1, Jan. 2, Mar. 28, May 5, Dec. 25

THE COUNTRY CODE

GUARD AGAINST THE RISK OF FIRE. Great damage is done every year to crops, plantations, woodlands, and heaths. A match or cigarette thrown away or a pipe carelessly knocked out, picnic fires not properly put out or lighted near dry crops, can quickly start a blaze.

FASTEN ALL GATES. If animals get out of a field they stray. As a result they may do serious damage to crops, suffer injury on the roads, or eat food that is harmful.

KEEP DOGS UNDER CONTROL. Animals are easily frightened, even by small, playful dogs. Stillbirths may be the result.

KEEP TO THE PATHS ACROSS FARM LAND. Crops are damaged by treading; flattened crops are difficult to harvest. Grass is a valuable crop.

AVOID DAMAGING FENCES, HEDGES, AND WALLS. If these are damaged, gaps will be caused. Where a man goes, an animal may follow.

LEAVE NO LITTER. Litter is not just unsightly, but often a danger as well. Broken glass and tins may injure animals and harm machinery.

SAFEGUARD WATER SUPPLIES. Countrymen often depend on wells and streams for water for themselves and for their animals.

PROTECT WILD LIFE, PLANTS, AND TREES. Wild animals should not be disturbed, plants uprooted, or trees treated roughly.

GO CAREFULLY ON COUNTRY ROADS. If there is no footpath, walkers are generally safer on the right, facing on-coming traffic. Care and patience are needed by motorists when passing farm animals.

RESPECT THE LIFE OF THE COUNTRYSIDE. Many of the machines and much of the business stock on which the farmer depends for his livelihood have to be kept in the open. Take care not to damage them.

THE BEAUFORT SCALE OF WIND FORCE

Beaufort number	*Wind*	*Effect on land*	*Speed*	
			mile/h	*Knots*
0	Calm	Smoke rises vertically	Less than 1	Less than 1
1	Light air	Direction shown by smoke but not by wind vanes	1–3	1–3
2	Light breeze	Wind felt on face; leaves rustle; wind vanes move	4–7	4–6
3	Gentle breeze	Leaves and twigs in motion; wind extends light flag	8–12	7–10
4	Moderate breeze	Raises dust, loose paper and moves small branches	13–18	11–16
5	Fresh breeze	Small trees in leaf begin to sway	19–24	17–21
6	Strong breeze	Large branches in motion; whistling in telegraph wires; difficulty with umbrellas	25–31	22–27
7	Moderate gale	Whole trees in motion; difficult to walk against wind	32–38	28–33
8	Fresh gale	Twigs break off trees; progress impeded	39–46	34–40
9	Strong gale	Slight structural damage occurs; chimney pots and slates blown off	47–54	41–47
10	Whole gale	Trees uprooted and considerable structural damage	55–63	48–56
11	Storm	Widespread damage, seldom experienced in England	64–75	57–65
12	Hurricane	Winds of this force only encountered in tropical revolving storms	Above 75	Above 65

ECLIPSES 1975

1. A partial eclipse of the Sun on May 11. It will be visible from North Africa, Europe including the British Isles, Greenland, the extreme north of Canada, northern Asia and the north-western part of Alaska. The eclipse begins at 05h 08m and ends at 09h 25m. At the time of maximum eclipse, 0·86 of the Sun's diameter is obscured.
2. A total eclipse of the Moon on May 25. It is visible from the western half of Africa, the south-western part of Europe, the Atlantic Ocean, the southern part of Greenland, Antarctica, South America, North America except the northern part, the Pacific Ocean, New Zealand and the extreme eastern part of Australia. The partial eclipse begins at 04h 00m and ends at 07h 36m. Totality lasts from 05h 03m to 06h 33m.
3. A partial eclipse of the Sun on November 3. It will be visible from southern South America and most of Antarctica. The eclipse begins at 11h 15m and ends at 15h 15m. At the time of maximum eclipse 0·96 of the Sun's diameter is obscured.
4. A total eclipse of the Moon on November 18–19. It will be visible from the western part of Australia, most of Asia, the Indian Ocean, Africa, Europe including the British Isles, the Atlantic Ocean, Greenland, the arctic regions, North America except the western part, and most of South America. The partial eclipse begins at 18d 20h 39m and ends at 19d 00h 08m. Totality lasts from 18d 22h 03m to 18d 22h 44m.

'Royal Worcester England' added 1891

James Hadley & Sons 1896–1905

G. Grainger & Co, c.1839–1902

Many of the marks found on ceramics are merely the marks of painters and workman. Even when identified, they are not a sure guide to the place of manufacture, as these people would work in many different factories in the course of their careers. The throwers or "repairers" (the workers who assembled the various parts of figures, etc.) invariably used a mark scratched in the body of the ware prior to the biscuit-firing. These marks when *under* the glaze can safely be treated as genuine. A mark which has been ground in after firing, in order to deceive, will not have the characteristic burr or raised edge produced when soft clay is scratched.

Painters and gilders would generally use one of the colours in their palette or gilt to mark the wares upon which they worked. This was probably for the benefit of the management as payment was often on a piecework basis.

The marks used on English wares were applied in several different ways—by incising, impressing, painting, or by transfer-printing *under* the glaze

MARKS ON ENGLISH POTTERY AND PORCELAIN

Caughley (Salop) 1775–1799

in blue (also in green after 1850). Marking by painting, transfer-printing, or stencilling *over* the glaze in enamel colours is always liable to be fraudulent as these types of mark can be added at any time after the piece has been made.

From 1842–83 many manufacturers' wares were marked with the "diamond-mark", illustrated above. This was an indication that the design had been registered with the British Patent Office. Ceramics was Class IV, indicated in the topmost section of the mark. This gave copyright protection for three years. After 1883 the mark was written as a number, *e.g.*, Rd. No. 12345.

A further indication of late wares is the inclusion of the word "England" in the mark. This was necessary to comply with the American McKinley Tariff Act of 1891. The full term "Made in England" is an indication of 20th century manufacture.

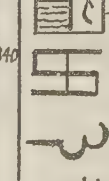
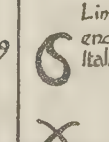
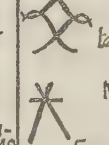
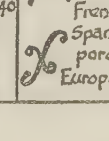
Samson & Co.
1845~









It was not until the adoption on Meissen porcelain in 1723 of the "K.P.M." and in 1724 of the cross-swords (from the arms of Saxony) that marks began to be used at all regularly in Europe. The placing of the mark underneath and the use of blue are clear indications that the Chinese model was being followed. The Meissen practice was then adopted by other German and, indeed, by most porcelain factories of repute.

Throughout the 18th century the practice was never regularised, and except for a brief period in France from 1766, and two years later in the Dutch town of Delft, there was no compulsory marking of wares. The factories of repute, proud of their productions, added a recognised mark and even used it, as at Nymphenburg, as part of the decoration. Their imitators left their wares unmarked or employed a mark likely to be mistaken for a more famous one: Weesp and Tournay both adopted a version of the Meissen crossed-swords;

the torches of La Courtille, the hooks of Rauenstein, the hayforks of Rudolstadt, the "L"s of Limbach, and the "W" of Wallendorf, were all drawn in such a way as to resemble the Meissen mark.

The firm of Samson & Co. was established in Paris in 1845, claiming to make "Reproductions of Ancient Works emanating from the Museums and from Private Collections". When imitating the true hard-paste porcelain of the Far East or the Continent, Samson's wares are difficult to detect, due to their being made from similar materials, whereas his reproductions of such English factories as Bow, Chelsea, and Derby are more easily recognised as fakes. Unfortunately the range of Samson's marks, illustrated above, do not appear to have been regularly used, or, as is sometimes the case, the original mark has been removed by grinding or by etching away with acid, and a replica of a known genuine mark added.

Factory marks in the Western sense are practically unknown on Chinese porcelain wares, while those purporting to record the period of manufacture are so liable to be "commemorative", or even deliberately fraudulent, as to be a frequent cause of dispute among students. Marks of the Ming Chinese Emperors, Hsüan Tê, Ch'êng Hua and Chia Ching are commonly found on wares of the reign of the Ch'ing Emperor K'ang Hsi, while the reign name of K'ang Hsi himself, rare on the abundant porcelain of his period, is chiefly found on 19th- and 20th-century wares.

Under the rule of the Ming Emperors (1368–1644) the Sung ideals in pottery were largely rejected in favour of the vogue for fine-grained white porcelain heralding the beginning of a new period in Chinese ceramic history with its centre in the town of Ching-tê Chên in Kiangsi province where a new Imperial factory was started in 1369 with a prolific output of early Ming blue-and-white

and fine enamel-painted porcelain both for the court and later for general use and export.

Following the fall of the Ming Dynasty in 1644 their declining culture was revived by the Ch'ing Emperor K'ang Hsi (1662—1722) who was a great patron of the arts. The European influence of the French and Netherlandish Jesuits at his courts is seen in the Baroque character of the early Ch'ing porcelain.

There was a backward-looking tendency during the reigns of Yung-Chêng (1723–35) and Ch'ien Lung (1736–95) when exact copies of the classical Sung wares and the early Ming painted porcelain were made.

The Imperial porcelain of the 19th century was as a rule carefully and weakly correct in following earlier styles and models. The factory was burnt in 1853 by the T'ai-ping rebels and hardly recovered before the 1911 revolution ended the Dynasty.

ABBREVIATIONS IN COMMON USE

A

a. = area; acre(s); are (100 sq. metres).
A.A. = Automobile Association; Alcoholics Anonymous.
AAA = Amateur Athletics Association.
A.A.C.C.A. = Associate of the Association of Certified and Corporate Accountants.
A.A.I. = Associate of the Chartered Auctioneers' and Estate Agents' Institute.
A.A.L.P.A. = Associate of the Incorporated Society of Auctioneers and Landed Property Agents.
A. and M. = Ancient and Modern (Hymns).
A.B. = able-bodied seaman; *Artium Baccalaureus* (Bachelor of Arts).
A.B.A. = Amateur Boxing Association.
A.B.A.A. = Associate of the British Association of Accountants.
ABM = anti-ballistics missile defence system.
Abp. = Archbishop.
abr. = abridged.
ABRC = Advisory Board for Research Councils.
abs. = absolute.
a.c. (*or* A.C.) = alternating current.
A.C.A. = Associate of the Institute of Chartered Accountants.
A.C.I.S. = Associate of the Institute of Chartered Secretaries and Administrators.
A.Comm.A. = Associate of the Society of Commercial Accountants.
ACT = Advisory Council on Technology.
ACTH = adreno-cortico-trophic hormone.
A.C.W.A. = Associate of the Institute of Cost and Management Accountants.
A.D. = *anno domini* (in the year of our Lord).
A.Dip. Art. Ed. = Advanced Diploma in Art Education.
A.Dip. Ed. = Advanced Diploma in Education.
A.D.C. = Aide-de-Camp.
Adm. = Admiral.
advt. (*or* adv.) = advertisement.
A.F.A.S. = Associate of the Faculty of Architects and Surveyors.
AEA = Atomic Energy Authority (UK).
AEC = Atomic Energy Commission (US).
AERE = Atomic Energy Research Establishment.
aet. (*or* aetat.) = *aetatis* (of age).
A.F.C. = Air Force Cross.
A.F.L. = American Federation of Labour.
A.F.M. = Air Force Medal.
AFRASEC = Afro-Asian Organisation for Economic Cooperation.
A.G. = Adjutant-General.
AGR = Advanced Gas-cooled Reactor.
A.H. = *anno Hegirae* (in the year of the Hegira).
A.I.A. = Associate of the Institute of Actuaries.
A.I.A.C. = Associate of the Institute of Company Accountants.
A.I.B. = Associate of the Institute of Bankers.
A.I.B.P. = Associate of the Institute of British Photographers.
A.I.C.E. = Associate of the Institution of Civil Engineers.
A.I.C.S. = Associate of the Institute of Chartered Shipbrokers.
AID = Agency for International Development (U.S.).
A.I.M.E. = Associate of the Institution of Mining Engineers.
A.I.Mech.E. = Associate of the Institution of Mechanical Engineers.
A.I.N.A. = Associate of the Institution of Naval Architects.
A.Inst.P. = Associate of the Institute of Physics.
A.I.Q.S. = Associate of the Institute of Quantity Surveyors.
A.L.A. = Associate of the Library Association.
A.L.S. = Associate of the Linnean Society.
alt. = altitude.
A.M. = *anno mundi* (in the year of the world); *Artium Magister* (Master of Arts); amplitude modulation.
a.m. = *ante meridiem* (before noon).
A.M.D.G. = *ad majorem Dei glorium* (to the greater glory of God).
amp. = ampere(s).
A.M.I.C.E. = Associate Member of the Institution of Civil Engineers.
A.M.I.Chem.E. = Associate Member of the Institution of Chemical Engineers.
A.M.I.E.E. = Associate Member of the Institution of Electrical Engineers.
A.M.I.Mech.E. = Associate Member of the Institution of Mechanical Engineers.
A.M.I.Mun.E. = Associate Member of the Institution of Municipal Engineers.
ANC = African National Congress.
anc. = ancient.
anhyd. = anhydrous.
anon. = anonymous.
ANZAC = Australian and New Zealand Army Corps.
ANZUS = Australian, New Zealand and U.S. Defence Pact (Pacific Security Treaty).
A.O.C. = Air Officer Commanding.
A.P. = Associated Press.
APT = Advanced Passenger Train.
aq. = aqueous.
A.R.A. = Associate of the Royal Academy.
A.R.A.D. = Associate of the Royal Academy of Dancing.
A.R.A.M. = Associate of the Royal Academy of Music.
A.R.B.S. = Associate of the Royal Society of British Sculptors.
ARC = Agricultural Research Council.
A.R.C.M. = Associate of the Royal College of Music.
arch. = archipelago.
A.R.C.O. = Associate of the Royal College of Organists.
A.R.C.Sc. = Associate of the Royal College of Science.
A.R.I.B.A. = Associate of the Royal Institute of British Architects.
A.R.I.C. = Associate of the Royal Institute of Chemistry.
A.R.I.C.S. = Associate of the Royal Institution of Chartered Surveyors.
A.R.P.S. = Associate of the Royal Photographic Society.
A.R.W.S. = Associate of the Royal Society of Painters in Water Colours.
A.S. (*or* AS) = Anglo-Saxon.
A.S.A. = Amateur Swimming Association.
ASDIC = Anti-submarine detector indicator.
ASEAN = Association of South-East Asian Nations (Indonesia, Malaysia, Philippines, Singapore, Thailand).
ASH = Action on Smoking and Health.
ASLIB = Association of Special Libraries and Information Bureaux.
ASPAC = Asian and Pacific Council.
A.T.C. = Air Training Corps.
A.T.D. = Art Teachers Diploma.
atm. = atmospheric pressure.
ATP = adenosine triphosphate.
at.wt. = atomic weight.
A.U.C. = *ab urbe condita* (from the founding of the City (Rome)), *or*, *anno urbis conditae* (in the year of the founding of the City).
av. = average.
AV = Authorized Version.
A.W.O.L. = Absent Without Leave.

B

b. = born; bowled.
B.A. = Bachelor of Arts.
B.A.A. = British Astronomical Association; British Airports Authority.
BAC = British Aircraft Corporation.
BAF = British Athletic Federation.
B.A.O. = Bachelor in the Art of Obstetrics.
BAOR = British Army of the Rhine.
B.Arch. = Bachelor of Architecture.

Bart. (*or* Bt.) = Baronet.
B.B. = Boys' Brigade.
B.B.C. = British Broadcasting Corporation.
B.C. = before Christ; British Columbia.
B.Ch. (*or* Ch.B.) = Bachelor in Surgery.
B.C.L. = Bachelor in Civil Law.
B.Com. = Bachelor of Commerce.
B.D. = Bachelor in Divinity.
B.D.A. = British Dental Association.
Bde. = Brigade.
B.D.S. (*or* B.Ch.D.) = Bachelor in Dental Surgery.
BEA = British European Airways.
B.Ed. = Bachelor of Education.
B.E.M. = British Empire Medal.
B.Eng. = Bachelor of Engineering.
BGC = British Gas Corporation.
BIM = British Institute of Management.
BIS = Bank for International Settlements.
BISRA = British Iron and Steel Research Association.
B.Litt. = Bachelor in Letters.
B.M. = Bachelor in Medicine; British Museum.
B.M.A. = British Medical Association.
B.M.C. = British Motor Corporation.
B.Mus. = Bachelor in Music.
B.N.C. = Brasenose College, Oxford.
BNEC = British National Export Council.
BOAC = British Overseas Airways.

b.p. = boiling point.
Bp. = Bishop.
B.Phil. = Bachelor of Philosophy.
Br. (*or* Brit.) = British.
Brit.Ass. = British Association for the Advancement of Science.
B.R. = British Railways; British Rail.
B.R.B. = British Rail Board.
B.R.C.S. = British Red Cross Society.
B.R.S. = British Road Services.
B.Sc. = Bachelor of Science.
BSC = British Steel Corporation.
B.S.I. = British Standards Institution.
BST = British summer time.
Bt. = Baronet; Brevet.
B.T.H.A. = British Travel and Holidays Association.
B.Th. = Bachelor in Theology.
Btu = British thermal unit.
B.V.M. = Blessed Virgin Mary.
B.V.M.S. = Bachelor in Veterinary Medicine and Surgery.
B.W.B. = British Waterways Board.

C

C. = Centigrade; Conservative.
c. = *circa* (about); centi- (10^{-2}).
C.A. = Chartered Accountant (Scottish Institute).
CABs = Citizens' Advice Bureaux.
Cal. = Calorie (nutritional kilogram-calorie).
cal. = calorie (gram-calorie used in physics and chemistry).
Cantab. = of Cambridge.
Cantuar. = of Canterbury.
cap. = capital letter; capitulum (chapter).
CAP = Common Agricultural Policy (Common Market).
CARD = Campaign Against Racial Discrimination.
CARIFTA = Caribbean Free Trade Area.
CATs = Colleges of Advanced Technology.
C.B. = Companion of the Order of the Bath.
C.B.E. = Commander of the Order of the British Empire.
CBI = Confederation of British Industry (replaces BEC, FBI and NABM).
C.C. = County Council; County Councillor; Chamber of Commerce.
cc = cubic centimetre(s).
CCPR = Central Council of Physical Recreation.
C.D. = Civil Defence.
C.D.C. = Commonwealth Development Corporation.
C.D.S. = Chief of Defence Staff; Campaign for Democratic Socialis.
CDU = Christian Democratic Union (W. Ger.).
C.E. = Civil Engineer; Christian Era.
CEAO = West African Economic Community.
CEGB = Central Electricity Generating Board.
CENTO = Central Treaty Organisation.
centi = one-hundreth part (10^{-2}).
CERN = European Organisation for Nuclear Research.
CET = Central European Time; Common External Tariff (Common Market).
C.F. = Chaplain to the Forces.
cf. = *confer* (compare).
C.G.M. = Conspicuous Gallantry Medal.
C.G.S. = Chief of General Staff.
cgs = centimetre-gram-second.
CGT = Confédération Générale du Travail (French TUC).
C.H. = Companion of Honour.
Ch.Ch. = Christ Church.
Ch.M. = Master in Surgery.
C.I. = Lady of Imperial Order of the Crown of India; Channel Islands.
CIA = Central Intelligence Agency (US).
CID = Criminal Investigation Department.
C.I.E. = Companion of the Order of the Indian Empire.
Cie = Compagnie (Company).
c.i.f. = cost, insurance and freight.
C.-in-C. = Commander-in-Chief.
CIO = Congress of Industrial Organisations (US)
CIR = Commission on Industrial Relations.
C.L. = Companion of Literature.
C.L.B. = Church Lads' Brigade.
cm = centimetre(s).
C.M.G. = Companion of the Order of St. Michael and St. George.
C.M.S. = Church Missionary Society.
CNAA = Council for National Academic Awards.
CND = Campaign for Nuclear Disarmament.
C.O. = Commanding Officer; Conscientious Objector.
Co. = County; Company.
c/o = care of.
C.O.D. = Cash on Delivery.
C. of E. = Church of England.
COI = Central Office of Information.
CoID = Council of Industrial Design.
COMECON = Council for Mutual Economic Assistance (East European).
Con. (*or* C.) = Conservative.
corr. = corrected.
COSPAR = Committee on Space Research.
CP = Communist Party.
CPAG = Child Poverty Action Group.
CPC = Communist Party of China.
C.P.R.E. = Council for the Protection of Rural England.
CPSU = Communist Party of the Soviet Union.
crit. = critical.
crystl. = crystalline.
C.S.C. = Conspicuous Service Cross.
C.S.E. = Certificate of Secondary Education.
C.S.I. = Companion of the Order of the Star of India.
CSP = Council on Scientific Policy.
CSU = Christian Social Union (W.Ger.).
C.T. = Civic Trust.
C.T.C. = Cyclists' Touring Club.
CTR = Controlled thermonuclear research.
cu. = cubic.
C.V.O. = Commander of the Royal Victorian Order.
cwt. = hundredweight.

D

d. = *denarius* (penny), *denarii* (pence); died; daughter.
DAC = Development Assistance Committee (of OECD).
D.A.R. = Daughters of the American Revolution.
dB = decibel(s).
D.B.E. = Dame Commander of Order of British Empire.
D.C. = District of Columbia.
d.c. (*or* D.C.) = direct current.
D.C.L. = Doctor in Civil Law.
D.C.M. = Distinguished Conduct Medal.
D.C.M.G. = Dame Commander, Order of St. Michael and St. George.
D.C.V.O. = Dame Commander of the Royal Victorian Order.
D.D. = Doctor in Divinity.
D.D.R. = German Democratic Republic (E. Ger.).
D.D.S. = Doctor in Dental Surgery.
DDT = Dichloro-diphenyl-trichloro-ethane.
DES = Department of Education and Science.

deca = ten times.
deci = one-tenth (10^{-1}).
del. = *delineavit* (he drew it).
D.ès L. = Docteur ès Lettres.
D.ès Sc. = Docteur ès Sciences.
D.F.C. = Distinguished Flying Cross.
D.F.M. = Distinguished Flying Medal.
D.G. = *dei gratie* (by the grace of God).
DIA = Design and Industries Association.
dil. = dilute.
Dip.Ed. = Diploma in Education.
Dip. H.E. = Diploma in Higher Education.
Dip.Tech. = Diploma in Technology.
DKP = Communist Party (W. Germany).
D.L. = Deputy-Lieutenant.

FDP = Free Democratic Party (W. Ger.).
Fed. = Federation; Federal.
ff. = folios; and the following pages; fortissimo.
F.F.A.R.C.S. = Fellow of the Faculty of Anaesthetics, Royal College of Surgeons.
F.F.R. = Fellow of the Faculty of Radiologists.
F.G.S. = Fellow of the Geological Society.
F.H. = Fire Hydrant.
F.H.S. = Fellow of the Heraldry Society.
F.I.A. = Fellow of the Institute of Actuaries.
F.I.B. = Fellow of the Institute of Bankers.
F.I.B.P. = Fellow of the Institute of British Photographers.
F.I.C.S. = Fellow of the Institute of Chartered Shipbrokers.
F. Inst.F. = Fellow of the Institute of Fuel.
F.Inst.P. = Fellow of the Institute of Physics.
F.Inst.Pet. = Fellow of the Institute of Petroleum.
F.I.Q.S. = Fellow of the Institute of Quantity Surveyors.
F.I.R.E. = Fellow of the Institute of Radio Engineers.
FIS = Family Income Supplement.
F.J.I. = Fellow of the Institute of Journalists.
F.K.C. = Fellow of King's College (London).
fl. = *floruit* (flourished).
F.L.A. = Fellow of the Library Association.
F.L.S. = Fellow of the Linnaean Society.
FM = Frequency modulation.
FMC = Federal Maritime Commission (US).
F.N.S. = Fellow of the Newtonian Society.
F.O. = Foreign Office.
fo. = folio.
f.o.b. = free on board.
F.O.P. = Friendship Oil Pipeline (E.Europe).
f.p. = freezing point.
F.P.S. = Fellow of the Pharmaceutical Society.
F.Ph.S. = Fellow of the Philosophical Society.
F.R.A.D. = Fellow of the Royal Academy of Dancing.
F.R.A.I. = Fellow of the Royal Anthropological Institute.
F.R.A.M. = Fellow of the Royal Academy of Music.
F.R.A.S. = Fellow of the Royal Astronomical Society.
F.R.Ae.S. = Fellow of the Royal Aeronautical Society.
F.R.B.S. = Fellow of the Royal Society of British Sculptors.
F.R.C.M. = Fellow of the Royal College of Music.
F.R.C.O. = Fellow of the Royal College of Organists.

F.R.C.O.G. = Fellow of the Royal College of Obstetricians and Gynaecologists.
F.R.C.P. = Fellow of the Royal College of Physicians of London.
F.R.C.P.Ed. = Fellow of the Royal College of Physicians of Edinburgh.
F.R.C.S. = Fellow of the Royal College of Surgeons of England.
F.R.C.S.Ed. = Fellow of the Royal College of Surgeons of Edinburgh.
F.R.C.V.S. = Fellow of the Royal College of Veterinary Surgeons.
F.R.E.S. = Fellow of the Royal Empire Society.
F.R.Econ.S. = Fellow of the Royal Economic Society.
F.R.F.P.S. = Fellow of the Royal Faculty of Physicians and Surgeons (Glas.).
F.R.G.S. = Fellow of the Royal Geographical Society.
F.R.H.S. = Fellow of the Royal Horticultural Society.
F.R.Hist.S. = Fellow of the Royal Historical Society.
F.R.I.B.A. = Fellow of the Royal Institute of British Architects.
F.R.I.C. = Fellow of the Royal Institute of Chemistry.
F.R.I.C.S. = Fellow of the Royal Institution of Chartered Surveyors.
F.R.M.S. = Fellow of the Royal Microscopical Society.
F.R.Met.S. = Fellow of the Royal Meteorological Society.
F.R.N.S. = Fellow of Royal Numismatic Society.
F.R.P.S. = Fellow of the Royal Photographic Society.
F.R.S. = Fellow of the Royal Society.
F.R.S.A. = Fellow of the Royal Society of Arts.
F.R.S.C. = Fellow of the Royal Society of Canada.
F.R.S.E. = Fellow of the Royal Society of Edinburgh.
F.R.S.L. = Fellow of the Royal Society of Literature.
FRTPI = Fellow of the Royal Town Planning Institute.
F.S.S.R. = Fellow of the Royal Statistical Society.
F.S.A. = Fellow of the Society of Antiquaries.
F.S.M.C. = Fellow of the Spectacle Makers Company.
F.T.I. = Fellow of the Textile Institute.
F.Z.S. = Fellow of the Zoological Society.

G

g. = gram(s).
GATT = General Agreement on Tariffs and Trade.
G.B.E. = Knight (*or* Dame) Grand Cross of the Order of the British Empire.
G.C. = George Cross.
G.C.A. = Ground Control Approach.
G.C.E. = General Certificate of Education.
G.C.B. = Knight (or Dame) Grand Cross of the Order of the Bath.
G.C.I.E. = Knight Grand Commander of the Indian Empire.
G.C.M.G. = Knight Grand Cross of the Order of St. Michael and St. George.
G.C.S.I. = Knight Grand Commander of the Star of India.
G.C.V.O. = Knight (*or* Dame) Grand Cross of the Royal Victorian Order.
GDP = gross domestic product.
GDR = German Democratic Republic (E. Ger.).
Gen. = General; Genesis.
eV = thousand million electron-volts.
G.H.Q. = General Headquarters.
G.I. = American soldier (from army term "Government Issue" applied to kit and equipment).
GLC = Greater London Council.
G.M. = George Medal.
G.M.C. = General Medical Council.
G.M.T. = Greenwich mean time.
GNP = gross national product.
G.O.C. = General Officer Commanding.
G.O.P. = Grand Old Party (US Republican Party).
G.P. = General Practitioner.
gr. = grain(s).
G.R.C.M. = Graduate of the Royal College of Music.
G.R.S.M. = Graduate of the Royal Schools of Music (Royal Academy and Royal College).
G.S.O. = General Staff Officer.
GTCs = Government Training Centres.
GYP = gross domestic income.

H

ha = hectare (100 ares).
H.E. = His Excellency; His Eminence: high explosive.
hecto = one hundred times (10^2).
H.H. = His (*or* Her) Highness.
hhd. = hogshead.
H.I.M. = His Imperial Majesty.
H.J.S. = *Hic jacet sepultus* (Here lies buried).
H.M. = His (*or* Her) Majesty.
H.M.A.S. = Her Majesty's Australian Ship.
H.M.I. = Her Majesty's Inspector.
H.M.L. = Her Majesty's Lieutenant.
H.M.S = Her Majesty's Ship; Her Majesty's Service.
H.M.S.O. = Her Majesty's Stationery Office.
H.N.C. = Higher National Certificate.
H. of C. = House of Commons.
H. of L. = House of Lords.
Hon. = Honourable; Honorary.
hp = horsepower.
H.P. = Hire purchase.
H.R. = House of Representatives (US).
H.R.H. = His (*or* Her) Royal Highness.
H.S.E. = *Hic sepultus est* (Here lies buried).
H.T. = high tension.
HTR = high-temperature reactor (type of nuclear power station).
H.V. = health visitor.
H.W.M. = high water mark.

I

IADB = Inter-American Development Bank.
IAEA = International Atomic Energy Agency (UN).
IATA = International Air Transport Association.
ib. (*or* ibid.) = *ibidem* (in the same place).
IBA = Independent Broadcasting Authority.
IBERLANT = Iberian Atlantic Command (NATO).
IBRD = International Bank for Reconstruction and Development (World Bank) (UN).
ICAO = International Civil Aviation Organisation (UN).
ICBM = Intercontinental ballistic missile.
ICEM = Intergovernmental Committee for European Migration.
ICFTU = International Confederation of Free Trade Unions.
ICI = Imperial Chemical Industries.
ICJ = International Court of Justice (UN).
ICRC = International Committee of the Red Cross.
ICSU International Council of Scientific Unions.
ICT = International Computers and Tabulators.
ICY = International Co-operation Year (1965).
Id. = *idem* (the same).
IDA = International Development Association (UN).
i.e. = *id est* (that is).
IFC = International Finance Corporation (UN).
Ign. = *ignotus* (unknown).
IGY = International Geophysical Year (1957–8).
IHS = *Iesus Hominum Salvator* (Jesus Saviour of men)—repr. a Greek abbrev. of the word Jesus.
ILEA = Inner London Education Authority.
ILO = International Labour Organisation (UN).
I.L.S. = Instrument Landing System.
IMCO = Intergovernmental Maritime Consultative Organisation (UN).
IMF = International Monetary Fund (UN).
Inc. = Incorporated.
Incog. = *incognito* (unknown, unrecognised).
inf. = infinitive; *infra* (below).
in loc. (*in loco*) = in its place.
I.N.R.I. = *Iesus Nazarenus, Rex Iudaeorum* (Jesus of Nazareth, King of the Jews).

Inst. = Institute; Institution.
inst. = instant (the present month).
Interpol = International Criminal Police Commission (HQ in Paris).
Intelsat = International Telecommunications Satellite Consortium.
I.O.M. = Isle of Man.
I.O.W. = Isle of Wight.
IOU = I owe you.
IQ = intelligence quotient.
IQSY = International Years of the Quiet Sun.
I.R. = Inland Revenue.
I.R.A. = Irish Republican Army.
IRBM = Intermediate-range ballistic missile.
IRC = International Red Cross; Industrial Reorganisation Corporation (wound up 1970).
IRDA = Industrial Research and Development Authority.
I.S.O. = Imperial Service Order; International Standardisation Organisation.
I.T.A. = Independent Television Authority; Institute of Travel Agents; Industrial Transport Association; Invalid Tricycle Association.
I.T.O. = International Trade Organisation.
I.T.U. = International Telecommunication Union (UN).
ITV = Independent Television.
IWA = Inland Waterways Association.

J

J. = Judge; Jet (aircraft).
J.P. = Justice of the Peace.

K

K = Kelvin.
K. = Köchel numeration (of Mozart's works).
KANU = Kenya African National Union.
k = kilo = thousand.
K.B.E. = Knight Commander of the Order of the British Empire.
K.C. = King's Counsel.
kc. = kilocycle(s).
K.C.B. = Knight (or Dame) Commander of the Order of the Bath.
K.C.I.E. = Knight Commander of the Order of the Indian Empire.
K.C.M.G. = Knight Commander of the Order of St. Michael and St. George.
K.C.S.I. = Knight Commander of the Star of India.
K.C.V.O. = Knight Commander of the Royal Victorian Order.
K.G. = Knight of the Order of the Garter.
KGB = Soviet State Security Service.
kg = kilogram(s).
kilo = one thousand times (10^3).
KJV = King James Version.
K.K.K. = Ku Klux Klan.
km = kilometre(s).
k.o. = knock out (boxing).
K.P. = Knight of the Order of St. Patrick.
K.T. = Knight of the Order of the Thistle.
Kt. = knight.
kV = kilovolt(s).
kW = kilowatt(s).
kWh = kilowatt hour(s).

L

L. (*or* Lib.) = Liberal.
L.A. = Local Authority.
Lab. = Labour.
L.A.C. = London Athletic Club.
LAFTA = Latin American Free Trade Association.
LAMDA = London Academy of Music and Dramatic Art.
lat. = latitude.
lb. = *libra* (pound). *librae* (pounds).
lbf = pound-force.
l.b.w. = leg before wicket.
l.c. = lower case (small letter(s)).
LCC = London County Council.
L.C.J. = Lord Chief Justice.
L.C.P. = Licentiate of the College of Preceptors.
L.D.S. = Licentiate in Dental Surgery.
L.ès L. = Licencié ès Lettres.
L.F.B. = London Fire Brigade.
L.H.D. = *Litterarum Humaniorum Doctor* (Doctor of Humane Letters).
Lic.Med. = Licentiate in Medicine.
Lic.S. = Licentiate in Surgery.
Lit.Hum. = *Literae Humaniores* (Study of the Classics).
Litt.D. = *Litterarum Doctor* (Doctor of Letters; Doctor in Letters (Camb.)).
LL.B. = *Legum Baccalaureus* (Bachelor of Laws).
LL.D. = *Legum Doctor* (Doctor of Laws; Doctor in Law (Camb.)).
L.M. = Licentiate in Midwifery.
loc.cit. = *loco citato* (in the place sited).
log. = logarithm.
long. = longitude.
L.R.A.D. = Licentiate of the Royal Academy of Dancing.
L.R.A.M. = Licentiate of the Royal Academy of Music.
L.R.C.M. = Licentiate of the Royal College of Music.
L.R.C.P. = Licentiate of the Royal College of Physicians.
L.R.C.S. = Licentiate of the Royal College of Surgeons.
L.R.C.V.S. = Licentiate of the Royal College of Veterinary Surgeons.
L.S. = *loco sigilli* (place of the seal).
L.S.A. = Licentiate of the Society of Apothecaries.
L.s.d. = *Librae, solidi, denarii* (Pounds, shillings, pence).
LSD = Lysergic acid diethylamide
L.S.E. = London School of Economics.
L.S.O. = London Symphony Orchestra.
L.T.A. = Lawn Tennis Association.
LTB = London Transport Board.
L.Th. = Licentiate in Theology.
Lt.-Gen. = Lieutenant-General.
L.W.M. = lower-water mark.
LXX = Septuagint.

M

M. = Member; Monsieur; mark (German coin); *meridies* (noon); mega (million times).
m = metre(s).
m. = married; masculine; million.
M.A. = Master of Arts.
MAOT = Member of the Association of Occupational Therapists.
M.A.O. = Master in the Art of Obstetrics.
max. = maximum.
M.B. = Bachelor in Medicine.
M.B.A. = Master of Business Administration.
M.B.E. = Member of the Order of the British Empire.
M.C. = Military Cross; Master of Ceremonies.
Mc = million cycles, *or* megacycle.
M.C.C. = Marylebone Cricket Club.
M.Ch. = Master in Surgery.
M.Ch.D. = Master in Dental Surgery.
M.Ch.Orth. = Master in Orthopaedic Surgery.
M.Com. = Master of Commerce.
M.C.S.P. = Member of the Chartered Society of Physiotherapy.
M.C.T. = Member of the College of Technologists.
M.D. = *Medicineae Doctor* (Doctor in Medicine).
M.D.S. = Mas er in Dental Surgery.
M.Ed. = Master of Education.
M.E. = Middle English.
mega = one million times (10^6).
MeV = megaelectronvolt(s)
M.F.H. = Master of Foxhounds.
mg = milligram(s).
Mgr. = Monsignor.
MHD = magnetohydrodynamics.
micro = one-millionth part (10^{-6}).
M.I. = Military Intelligence.
M.I.C.E. = Member of the Institution of Civil Engineers.
M.I.Chem.E. = Member of the Institution of Chemical Engineers.
M.I.E.E. = Member of the Institution of Electrical Engineers.
milli = one-thousandth part (10^{-3}).
M.I.M.A. = Member of the International Marine Association.

M.I.Mar.E. = Member of the Institute of Marine Engineers.
M.I.Mech.E. = Member of the Institution of Mechanical Engineers.
M.I.Min.E. = Member of the Institution of Mining Engineers.
min. = minimum.
M.I.N.A. = Member of the Institution of Naval Architects.
M.Inst.Met. = Member of the Institute of Metals.
Min. Plenip. = Minister Plenipotentiary.
M.I.Mun.E. = Member of the Institution of Municipal Engineers.
MIRV = multiple independent re-entry vehicle.
M.Inst.T. = Member of the Institute of Transport.
M.I.T. = Massachusetts Institute of Technology.
M.I.T.M.A. = Member of the Institute of Trade Mark Agents.
M.I.W.M. = Member of the Institution of Works Managers.
M.J.I. = Member of the Institute of Journalists.
MKS = metre-kilogram-second system.
MKSA = metre-kilogram-second-ampere (Giorgi) system.
MLF = Multilateral Force.
Mlle = Mademoiselle.
MM. = Messieurs.
M.M. = Military Medal.
mm = millimetre(s).
Mme = Madame.
m.m.f. = magnetomotive force.
mmHg = millimetre(s) of mercury.
M.N. = Merchant Navy.
Mods. = Moderations (Oxford).
M.O.H. = Medical Officer of Health.
m.p. = melting point.
M.P. = Member of Parliament Military Police.
m.p.h. = miles per hour.
M.Phil. = Master of Philosophy.
M.P.S. = Member of the Pharmaceutical Society; Member of the Philological Society; Member of the Physical Society.
M.R. = Master of the Rolls.
M.R.A.S. = Member of the Royal Asiatic Society; Member of the Royal Academy of Science.
M.R.Ae.S. = Member of the Royal Aeronautical Society.
M.R.C. = Medical Research Council.
M.R.C.O.G. = Member of the Royal College of Obstetricians and Gynaecologists.
M.R.C.P. = Member of the Royal College of Physicians.
M.R.C.P.(E.) = Member of the Royal College of Physicians (Edinburgh).
M.R.C.S. = Member of the Royal College of Surgeons.
M.R.C.V.S. = Member of the Royal College of Veterinary Surgeons.
M.R.I. = Member of the Royal Institution.
M.R. Inst. Nav. = Member of the Royal Institute of Navigation.
MRTPI = Member of the Royal Town Planning Institute.
M.S. = Master in Surgery.
Ms., Mss. = Manuscript, Manuscripts.
M.S.A. = Mutual Security Agency.
M.Sc. = Master of Science.
M.T.B. = Motor Torpedo Boat.
Mus.B. = *Musicae Baccalaureus* (Bachelor in Music).
Mus.D. = *Musicae Doctor* (Doctor in Music).
MV = million volts *or* megavolt.
M.V.O. = Member of the Royal Victorian Order.
MW = million watts *or* megawatt.
M.W.B. = Metropolitan Water Board.

N

NAAFI = Navy, Army and Air Force Institutes.
N.A.B.M. = National Association of British Manufacturers.
NADGE = Nato Air Defence Ground Environment Organisation.
nano = one-thousand-millionth part (10^{-9}).
NASA = National Aeronautics and Space Administration (US).
NATO = North Atlantic Treaty Organisation.
NATSOPA = National Society of Operative Printers and Assistants.
N.B. = *nota bene* (note well).
NBS = National Bureau of Standards (US).
NCB = National Coal Board.
NCC = Nature Conservancy Council.
N.C.O. = Non-commissioned Officer.
N.C.U. = National Cyclists' Union.
n.d. = no date (of books).
N.D.D. = National Diploma in Design.
NEA = Nuclear Energy Agency (OECD).
NEDC = National Economic Development Council.
NEL = National Engineering Laboratory.
Nem.con. = *Nemine contradicente* (no one contradicting = unanimously).
Nem.diss. = *Nemine dissentiente* (no one dissenting = unanimously).
NERC = Natural Environment Research Council.
Net. (*or* Nett.) = free from, or not subject to, any deductions.
NHS = National Health Service.
NIBMR = no independence before majority rule.
NIRC = National Industrial Relations Court.
NIRNS = National Institute for Research in Nuclear Science.
NLF = National Liberation Front (political arm of Vietcong in S. Vietnam).
NLL = National Lending Library for Science and Technology.
No. = *numero* (number).
non.seq. = *non sequitur* (it does not follow).
NPC = National Parks Commission; National Ports Council.
N.P. = Notary Public.
NPD = National Democratic Party (W. Ger.).
N.P.F.A. = National Playing Fields Association.
NPL = National Physical Laboratory.
N.R.A. = National Rifle Association.
NRDC = National Research Development Corporation.
N.S. = New Style in the calendar (in Gt. Britain since 1752).
N.S.P.C.C. = National Society for the Prevention of Cruelty to Children.
N.T. = New Testament; National Trust.
N.U.R. = National Union of Railwaymen.
N.U.T. = National Union of Teachers.
N.Y. = New York.
N.Z. = New Zealand.

O

OAPEC = Organisation of Arab Petroleum Exporting Countries.
OAS = Organisation of American States; Organisation de l'Armée Secrète (the clandestine army of the French colonists in Algeria).
OAU = Organisation of African Unity.
ob. = *obit* (died).
obs. = observed.
O.B.E. = Officer of the Order of the British Empire.
OBEV = Oxford Book of English Verse.
OCAM = Common African, Malagasy and Mauritanian Organisation.
OCAS = Organisation of Central American States.
OCTU = Officer Cadets' Training Unit.
ODECA = Organisation of Central American States.
OECD = Organisation for Economic Co-operation and Development.
O.E.D. = Oxford English Dictionary.
O.F.M. = *Ordo Fratrum Minorum* (Order of Friars Minor = Franciscan).
O.H.M.S. = On Her Majesty's Service.
O.M. = Member of the Order of Merit.
O.N.C. = Ordinary National Certificate.
O.P. = *Ordinis Praedicatorum* (Order of Preachers = Dominicans); opposite to prompter (stage term); out of print.
op. = *opus* (work).
op cit. = *opere citato* (in the work cited).
OPEC = Organisation of Petroleum Exporting Countries.
ORC = Overseas Research Council.
ORGEL = Organique et Eau Lourde (organic liquid and heavy water nuclear reactor).
O.S. = Old Style in calendar.
O.S.B. = *Ordo Sancti Benedicti* (Order of St. Benedict = Benedictines).
O.T. = Old Testament.
O.T.C. = Officers' Training Corps.
Oxon. = of Oxford.
oz. = ounce(s).

P

p = penny, pence (decimal system).
P.A. = Press Association.
PAYE = Pay as you earn (income tax scheme).
P.C. = Privy Councillor; Police Constable.
P.C.C. = People's Caretakers' Council (Nat. movement in Rhodesia).
p.c. = per cent.; postcard.
p.d. = potential difference.
pdl = poundal.
P.D.S.A. = People's Dispensary for Sick Animals.
P.E.N. = Poets, Playwrights, Essayists, Editors and Novelists (Club).
P.E.P. = Political and Economic Planning (Society).
per pro (*or* p.p.) = *per procurationem* (by proxy).
PFLP = Popular Front for the Liberation of Palestine.
Ph.D. = *Philosophiae Doctor* (Doctor of Philosophy).
pinx = *pinxit* (he painted).
P.L.A. = Port of London Authority.
PLP = Parliamentary Labour Party.
PLUTO = Pipe-line under the ocean.
P.M. = Prime Minister; Post master; *post meridiem* (afternoon).
P.M.O. = Principal Medical Officer.
P.N.E.U. = Parents' National Education Union.
P.O. = Post Office; postal order; Petty Officer.
P. & O. = Peninsular and Oriental Steamship Co.
P.O.W. = prisoner of war.
pp. = pages.
P.P.C. = pour prendre congé (to take leave).
P.Q. = Parliamentary Question.
P.P.S. = Parliamentary Private Secretary.
P.R. = Proportional Representation.
P.R.A. = President of the Royal Academy.
P.R.B. = Pre-Raphaelite Brotherhood.
PRC = People's Republic of China.
Pro tem. = *pro tempore* (for the time being).
Prox = *proximo* (of the next month).
P.R.S. = President of the Royal Society.
P.S. = *post scriptum* (postscript).
Ps. = Psalm.
Pss. = Psalms.
P.S.W. = Psychiatric Social Worker.
P.T. = Physical Training.
Pte. = Private.
P.T.O. = please turn over.

Q

Q. = Queen.
Q = 10^{18} British Thermal Units ($1{\cdot}05 \times 10^{21}$ joules).
Q.B. = Queen's Bench.
Q.C. = Queen's Counsel.
Q.E.D. = *quod erat demonstrandum* (which was to be demonstrated).
Q.E.F. = *quod erat faciendum* (which was to be done).
Q.E.I. = *quod erat inveniendum* (which was to be found).
q.l. (*or* q.pl) = *quantum libet* (*or quantum placet*) (as much as one pleases).
Q.M. = Quartermaster.
Q.M.C. = Queen Mary College.
q.s. = *quantum sufficit* (a sufficient quantity).
Q.S. = Quarter Sessions.
QSEs = Qualified Scientists and Engineers (*i.e.*, skilled manpower).
QSSs = Quasars (quasi stellar radio sources).
Q.T. = quiet (slang).
Qto. = quarto (folded in four).
QTOL = Quiet Take-off and Landing.
q.v. = *quod vide* (which see).

R

R. = Réaumur; *Rex* (King); *Regina* (Queen); Right (stage direction).
R.A. = Rear Admiral; Royal Academy; Royal Academician; Research Association; Right Ascension (astron.).
R.A.C. = Royal Automobile Club.
RAE = Royal Aircraft Establishment.
R.Ae.S. = Royal Aeronautical Society.
R.A.F. = Royal Air Force.
R.A.M. = Royal Academy of Music.
R.A.O.C. = Royal Army Ordnance Corps.
R.C. = Red Cross; Roman Catholic.
RCD = Regional Co-operation for Development (Pakistan, Turkey, Iran).
R.D. = Rural Dean; Royal Naval Reserve Decoration; Refer to Drawer.
R.D.I. = Designer for Industry of the Royal Society of Arts.
R.E. = Royal Engineers.
Reg. Prof. = Regius Professor.
R.E.M.E. = Royal Electrical and Mechanical Engineers.
Rep. = Representative; Republican.
R.G.S. = Royal Geographical Society.
r.h. = relative humidity.
R.H.S. = Royal Humane Society; Royal Horticultural Society.
R.Hist.S. = Royal Historical Society.
R.I. = Royal Institution; Royal Institute of Painters in Water Colours; Rhode Island; Religious Instruction.
R.I.B.A. = Royal Institution of British Architects.
R.I.I.A. = Royal Institute of International Affairs (Chatham House, London).
R.I.P. = *requiescat in pace* (may he rest in peace).
R.L.O. = Returned Letter Office.
R.M. = Royal Marines; Resident Magistrate.
R.M.C. = Royal Military College, Sandhurst.
r.m.s. = root mean square.
R.N. = Royal Navy.
RNA = ribonucleic acid.
R.N.L.I. = Royal National Lifeboat Institution.
Ro. = *recto* (on the right-hand page).
R.P. = Member of the Royal Society of Portrait Painters.
RRE = Royal Radar Establishment.
rpm = revolutions per minute.
R.S.A. = Royal Society of Arts; Royal Scottish Academician.
R.S.M. = Regimental Sergeant Major.
R.S.P.C.A. = Royal Society for the Prevention of Cruelty to Animals.
R.S.V.P. = *Répondez, s'il vous plaît* (An answer is requested).
R.S.W. = Royal Scottish Society of Painters in Water Colours.
Rt. Hon. = Right Honourable.
RTPI = Royal Town Planning Institute.
Rt. Rev. = Right Reverend (of a Bishop).
R.U. = Rugby Union.
RV = Revised Version.
R.W.S. = Royal Society of Painters in Water Colours.
R.Y.S. = Royal Yacht Squadron.

S

S. = *San, Santa, Santo,* or *São* (Saint); SS. = Saints.
s. = *solidus* (shilling), *solidi* (shillings).
S.A. = Salvation Army; Sex Appeal; South America; South Australia; South Africa; Société Anonyme (Limited).
SACEUR = Supreme Allied Commander Europe.
SACLANT = Supreme Allied Commander Atlantic.
SALT = Strategic Arms Limitation Talks.
Sarum = of Salisbury.
SAYE = Save as You Earn.
S.C. = qualified to admission to Staff College.
sc. = *scilicet* (namely).
Sc.D. = *Scientiae Doctor* (Doctor in Science).
S.C.F. = Senior Chaplain to the Forces.
S.C.M. = State Certified Midwife; Student Christian Movement.
SDLP = Social Democratic Labour Party (N. Ireland).
SEATO = South-East Asia Treaty Organisation.
SED = Socialist Unity Party (E. Ger.).
SET = selective employment tax.
S.G. = Solicitor-General; Scots Guards.
SGHWR = Steam Generating Heavy Water Reactor.
SHAPE = Supreme Headquarters Allied Powers in Europe.
SI = Système International d'Unités (International System of Units).
sic. = so written.

SINS = Ships Inertial Navigation System.
SOS = distress signal (wireless code signal, used especially by ships at sea).
s.p. = *sine prole* (without issue).
S.P.C.K. = Society for the Promotion of Christian Knowledge.
SPD = Social Democratic Party (W. Ger.).
sp. gr. = specific gravity.
sq. = square; *sequens* (the following).
sqq. = *sequentes, sequentia* (those following).
SRC = Science Research Council.
S.R.N. = State Registered Nurse.
SS. = Saints.
S.S. = Steamship.
S.S.C. = Solicitor before Supreme Court (Scotland).
SSCR = Social Science Research Council.
STAR = Satellites for Telecommunications, Applications and Research (European consortium).
S.T.D. = *Sacrae Theologiae Doctor* (Doctor of Theology); Subscriber Trunk Dialling.
St. = Saint; Street.
Ste = *Sainte* (Saint, feminine).
Stet = Let it stand (printing term).
s.t.p. = standard temperature and pressure.
S.T.P. = *Sacrae Theologiae Professor* (Professor of Divinity, old form of D.D.)
s.v. = *sub verbo* (under the entry).

T

TAB = Technical Assistance Board (UN).
TAVR = Territorial and Army Volunteer Reserve
T.B. = Tubercule bacillus (tuberculosis).
t.b. = torpedo boat.
T.C.D. = Trinity College, Dublin.
T.C.C.B. = Test and County Cricket Board.
T.D. = Territorial Decoration; Teachta Dála (Representative of the Dáil).
temp. = temperature.
T.F. = Territorial Force.
T.H. = Trinity House.
TNT = trinitrotoluene (high explosive).
Toc.H. = Talbot House.
tr. = transpose.
T.R.C. = Thames Rowing Club; Tithes Rent Charge.
T.T. = tubercular tested; teetotal.
TUC = Trades Union Congress.
TV = Television.
TVA = Tennessee Valley Authority.
T.V.W.B. = Thames Valley Water Board.
TWI = Training Within Industry for Supervisors.
T.Y.C. = Thames Yacht Club; Two-year Old (*or* Thousand Yards) Course.

U

U.A.M. = Afro-Malagasy Union.
U-boat = German submarine.
UCL = University College, London.
UCS = Upper Clyde Shipbuilders.
UDEAC = Central African Economic and Customs Union.
UDEAO = Customs Union of West African States.
UEAC = Union of Central African States.
UGC = University Grants Committee.
UHF = ultra-high frequency.
U.K. (*or* UK) = United Kingdom.
UKAEA = UK Atomic Energy Authority.
ult. = *ultimo* (of the last month).
UN *or* UNO = United Nations.
UNCTAD = United Nations Conference on Trade and Development.
UNDP = United Nations Development Programme.
UNEF = United Nations Emergency Force(s).
UNESCO = United Nations Education, Scientific, and Cultural Organisation.
UNICEF = United Nations Children's Fund.
UNIDO = United Nations Industrial Development Organisation.
UNRWA = United Nations Relief and Works Agency for Palestine Refugees.
UNTSO = UN Truce Supervision Organisation in the Middle East.
U.P. = United Press.
UPU = Universal Postal Union (UN).
U.S.A. (*or* USA) = United States of America.
USAEC = US Atomic Energy Commission.
U.S.P.G. = United Society for the Propagation of the Gospel.
USSR = Union of Soviet Socialist Republics (Russia).

V

V = volt(s).
v. = *vide* (see); *versus* (against).
V.A. = Vicar-Apostolic.
VAT = value added tax.
V. & A. = Victoria and Albert Museum, S. Kensington.
V.C. = Victoria Cross.
V.C.H. = Victoria County Histories.
V.D. = venereal disease; Volunteer Officers' Decoration.
v.d. = various dates.
V.E. Day = Victory in Europe Day, 8 May 1945.
Ven. = Venerable (of an Archdeacon).
verb. sap. = *verbum sapienti sat est* (a word to the wise is enough).
Very Rev. = Very Reverend (of a Dean or a Provost).
v.g. = very good.
v.h.c. = very highly commended.
V.H.F. = very high frequency.
V.I.P. = very important person.
viz. = *videlicet* (namely).
V.J. Day = Victory over Japan Day, 15 August 1945.
V.L. = Vice-Lieutenant (of a County).
V.M. = Virgin Mary.
V.M.H. = Victoria Medal of Honour (Royal Horticultural Society).
Vo. = *verso* (on the left-hand page).
V.P. = Vice-President.
V.R. = *Victoria Regina* (Queen Victoria).
v.r. = variant, *or* various reading.
V.S. = veterinary surgeon; vital statistics.
VTOL = vertical take-off and landing (aircraft).

W

W = watt(s).
Wasps = White Anglo-Saxon Protestants.
WCC = World Council of Churches.
W.E.A. = Workers' Educational Association.
WEU = Western European Union.
WFTU = World Federation of Trade Unions.
WHO = World Health Organisation (UN).
WMO = World Meteorological Organisation (UN).
W.O. = Warrant Officer.
W.R.A.C. = Women's Royal Army Corps.
W.R.A.F. = Women's Royal Air Force.
W.R.N.S. = Women's Royal Naval Service.
W.R.V.S. = Women's Royal Voluntary Service.
W.S. = Writer to the Signet.

Y

yd = yard(s).
Y.M.C.A. = Young Men's Christian Association.
Y.W.C.A. = Young Women's Christian Association.

Z

ZANU = Zimbabwe African National Union (Nat. movement in Rhodesia).
ZAPU = Zimbabwe African People's Union (Nat. movement in Rhodesia)

MEDICAL MATTERS

Here we give a brief summary of up-to-date medical knowledge, including some recent developments. It must not be allowed to replace your doctor, who should be consulted immediately if you are worried. An index ensures easy reference.

TABLE OF CONTENTS

Part I. Introduction 3–6

(*a*) How to use the Section
(*b*) New Views on Medicine

Part II. Diseases arranged according to their cause or to the area of the body affected with an introduction to each group of diseases under discussion 7–57

The Infectious Diseases 7
Physical Injuries 19
Drug Abuse and Drug Dependence 22
Diseases of the Blood 24
Diseases of the Heart and Blood-vessels 26
Diseases of the Respiratory System 31
Diseases of the Digestive Tract and Large Intestine 34
Diseases of the Liver 38
Diet 40
Weight/Height Scales 41
Nutritional Disorders 41
D seases of the Endocrine Glands 43
Diseases of the Urinary System 44
Diseases of the Nervous System 46
Mental Diseases 50
Diseases of the Skin 52
Diseases of the Joints 54
Eyes, Ears, Nose and Throat 55
Diseases of Women 55
Contraception 56

Part III. Special Topics 57–67

Infantile Undernutrition and the Brain 57
Sleeping and Dreaming 59
Parkinson's Disease 61
Child Abuse 63
Vitamin C and the Common Cold 66
Sudden Infant Death 67
Oral Contraceptives and Depression 69
A Balanced Diet 71

Part IV. Index and Glossary 74–78

An alphabetical index of diseases mentioned in the text of Part II, referring the reader to the appropriate page and column.

MEDICAL MATTERS

PART I. INTRODUCTION.

(a) HOW TO USE THE SECTION.

Diseases do not exist in watertight compartments, but doctors arrange them according either to their cause or the area of the body affected. This plan has been followed here, and at the beginning of each part an account of the group of diseases under discussion is given. Unless you know enough already, you would be wise to read it.

Here is some advice about your attitude to disease in general, and your use of this section in particular.

First of all, and obviously, no book is a substitute for the doctor, and when you are ill you must see him. There are good and bad doctors, competent and incompetent ones, just as in any other profession or trade; so choose a doctor you can trust, *and then believe what he tells you and carry out his advice.* There is no use complaining about the whole medical profession just because you are dissatisfied with your own G.P. If you are, you should change him.

Secondly, *never* believe what you hear from non-medical sources. Literally millions of people are made miserable every year by taking to heart nonsense told them by others, who may well be quite unaware of the harm they do, or even have the very best intentions. In any medical matter ask your doctor, and ignore your next-door neighbour's asked-for or unasked-for advice. Doctors are sometimes wrong, but they are much less likely to be wrong than someone without a medical education. Remember, too, that the statement that there is no cure for a disease does not necessarily mean that it is deadly: and it never means that nothing can be done to make it more tolerable. There is much more to modern doctoring than simply curing the curable.

Thirdly, don't try to diagnose your own trouble or decide what treatment you think you should have. This section will have failed completely in its intentions if it puts you in the position of a character described by an English humourist, who, from a medical dictionary, discovered that he had every disease listed in it with the solitary exception of housemaid's knee. Diseases which appear to the layman to have the "same" symptoms may be vastly different in seriousness: influenza and poliomyelitis, for example, may in the initial stages, appear very similar. So also may stomach ulcer and cancer of the stomach. No human being is infallible, but it is most important that you should go to the person who is best fitted to know—your doctor.

Lastly, you should not be misled into thinking that you can always tell the seriousness of a disease by the general appearance of the patient. Children, in particular, may have a high temperature, or even be delirious, on one day, and the next be out of bed and wanting to get back to school. On the other hand, many of the most dangerous fevers (as we shall see later) are accompanied by a low temperature and do not appear particularly dramatic in the initial stages. Thus a young woman who may be aware of nothing wrong but lack of energy and getting easily tired may be dangerously ill with tuberculosis of the lungs.

The best rule is to seek medical advice either when you have suddenly become ill with symptoms you don't understand or (and this is equally important) if you have gradually been feeling less fit over a period of time. Perhaps, too, it is wise to call your doctor if you have been ill with *anything* for more than three days. You should *not* call in a specialist before seeing your G.P., as is so often done in America and on the Continent. Specialists are very clever, but are naturally prejudiced in favour of their own subject; for example, an eye specialist will be predisposed to think of your headache in terms of eyestrain, an ear, nose, and throat specialist in terms of sinus trouble, and a psychiatrist in terms of mother-in-law trouble. Therefore you should first have a check from your G.P., who knows a little of all these things and probably a great deal about you and your past history. He will then advise you about a specialist if necessary.

(b) NEW VIEWS ON MEDICINE

(1) Body and Mind. In former times, or, at least during the nineteenth century, the body was regarded as a sort of machine belonging to you in much the same way that you own your watch. You went to your doctor and, in effect, said: "Now what on earth are you going to do about my stomach? "—and you spoke as if, somehow, your stomach didn't have anything to do with the *real* you—it was just an awkward thing that happened to be annoying you. But we know now that this is not so—that your body *is* you, that it is a fort fighting against such enemies as poisons, parasites, germs, cancer, and injuries. The defences are seriously weakened by not enough of the right kind of food, insufficient sleep, or by anxiety. Your anxieties and worries can kill you just as surely as the other agents, and can prevent recovery or retard it when you are already ill.

A stomach ulcer therefore is not just something that is happening to you, you are happening to it. Your fears, your jealousies, your hatreds, your inability to get on in life, can be (in some cases) just as harmful as germs or poisons—in fact, they act by setting free glandular poisons in your blood-stream. Scientists have discovered a reaction which they call the "stress response," and we now know that stress can ultimately lead to sickness or death without any bodily injury at all. Thus, Dr. L. J. Saul, a leading American doctor, writes: "Emotional stress in which there is no physical damage can produce responses which lead to actual damage and even to death." Rats in the laboratory can be killed through long exposure to fear caused by loud noises or other forms of shock without even being touched.

This stress factor is emphasised not because it is more important that the other enemies of the body or mind (it would be better to say body–mind), but because, as we shall see later, it does cause serious diseases, and, secondly, as mentioned already, it influences the process of recovery. A person who is afraid or has no hope is less likely to recover from pneumonia or another disease than one who is hopeful, who has peace of mind and confidence.

(2) New Views about Health. A great deal of nonsense has been talked about the healthy life; at one time we were told to take eighteen chews to each bite, to do deep breathing, to take plenty of exercise, to get lots of fresh air, to eat regularly (or to indulge in peculiar diets). But more recently,

eminent doctors have cast doubt on most of these fancies. Moderate exercise is necessary to health, but athletes who indulge in violent exercise have not always been noted for longevity. Fresh air is pleaasnt and stimulating, but, where actual breathing is concerned, it is no better than the air in most rooms. Certainly, one of the problems of our time is air pollution by smoke and Diesel fumes, which are highly dangerous, but at present we are considering ordinary fresh air in comparison with the air indoors, and, in this case, the experts say there is little difference so far as health is concerned.

A balanced diet containing correct amounts of the basic food substances is essential, but there is no evidence that when, or at what intervals, you eat makes the slightest difference—unless you are a sufferer from stomach ulcer, in which case it is necessary that the intervals between meals should not be too long. The whole business of having meals at fixed intervals is nothing but a social convention, and in modern life obviously a matter of convenience. *See* **Diet, P40, A Balanced Diet, Part III.**

Sleep, too, is a necessity. But different people require vastly different amounts of sleep. Some manage on as little as three hours, others seem to believe that they need ten or more. The importance of the dream process is referred to in **Part III** and in **Introduction to Psychology, Q15(1).**

In a number of studies of men and women who lived to a ripe old age it was found that the only factors in common between them were that they had a good balanced diet of healthy food, that they had contented minds, and that they were interested in something which gave them an aim in life. They also came of long-lived families—for living a long and healthy life depends partly upon heredity.

So the main rules of health are: (1) do not think too much about your health unless it gives you trouble; (2) have an interest in life and be prepared to sacrifice a lot for it (nothing useful has ever been done by those who are always "taking care" and being over-cautious); (3) eat a good balanced diet; (4) do not worry, and have a contented mind.

(3) New Drugs. A great surgeon, the first of the moderns, was Ambrose Paré, who died in 1590, and one of his best known sayings was: "I apply the dressing, but God heals the wound." He was quite right; for until about forty years ago, or even less, all the physician could do was to put the patient in as favourable a state as possible to enable his body to cure itself. That is to say, there were hardly any specific drugs—drugs that had a direct effect on the disease. There was quinine, discovered by the Spaniards in America, which was specific for malaria, and there were iron (specific for anæmia) and digitalis (specific for certain types of heart disease), but otherwise nothing until the nineteenth century, when Paul Ehrlich discovered salvarsan, which is specific for syphilis. Ehrlich died in 1914, having conceived the brilliant idea of drugs which he described as "magic bullets"—*i.e.*, drugs which, like bullets, would be aimed at the real cause of the disease. They would, that is to say, be specific.

Since then a large number of such drugs have been discovered. For example, the antibiotics, such as penicillin, discovered in 1928 by Fleming at St. Mary's Hospital, Paddington. Later, Florey and Chain in Oxford, helped in the war years by the vast resources of the American pharmaceutical industry, were able to make penicillin available to the public in sufficient quantities by new techniques of production. Penicillin is practically non-poisonous (although it is possible to become allergic to it, sometimes with serious results). It can kill some germs in a dilution of one part of penicillin to one hundred million parts of water; it is effective against streptococci, the cause of blood-poisoning, sepsis in wounds, and many other diseases: and also against the germs of anthrax, gonorrhœa, meningitis of some types, syphilis—a whole list of plagues which have troubled man for centuries. Blood-poisoning, whether from wounds or childbirth, used to be almost incurable—now the rate of cure is 80–90 per cent.; anthrax and gonorrhœa have an almost 100 per cent. rate of cure. In pneumonia the rate is about 90 per cent., and early syphilis can be cured in a week, instead of the previous two to three years.

But this was only the beginning. Other antibiotics—streptomycin, tetracycline, erythromycin, and many others—are helping to wipe out the terrible scourges of the human race, in particular, in the case of streptomycin, tuberculosis. The sulpha group of drugs—sulphadiazine, sulphadimidine, etc.—have also proved a great boon. Then there are the new drugs which have created a revolution in psychiatry—the tranquillisers which relieve anxiety, the drugs which clear up certain types of depression, and substances such as chlorpromazine which make it possible to nurse formerly violent patients in the wards of a general hospital. The antihistamine drugs help in many cases of allergy, the anticoagulants prevent further attacks of coronary thrombosis, and every year new and powerful aids in the fight against disease are discovered.

Of course, these potent new drugs are not without their concomitant risks. The doctor is trained to weigh the harm they can do against the disadvantages of *not* using them in any particular case. He should not use them for every trivial illness in which their only effect may be to shorten slightly the course of a condition which, left alone, would recover of itself. Yet in Britain and other technically-advanced countries indiscriminate prescribing is common, largely because of pressure on the doctor from his patients and the drug firms. The busy mother whose child has a mild sore throat is not going to see the child sweat it out when she knows from past experience that a dose of penicillin can remove the fever and most of the symptoms within twenty-four hours. She is unlikely to listen to the argument that the slower process is capable of increasing the body's resistance to future attacks, or that repeated administration of penicillin may create germs which are insensitive to it in a future emergency, or, worse still, produce an allergy to the drug. The thalidomide tragedy of 1962–3, when a new sedative, hailed as being both effective and safe (cases were quoted of would-be suicides who had taken up to 100 of the tablets without loss of life), resulted in the birth of children with undeveloped arms and legs to mothers who had used the drug in early pregnancy, and prolonged neuritis in some adults, has been quoted against the drug industry as an example of cut-throat competition allowing new preparations on the market before they had been exhaustively tested. But the truth is not quite so simple. There can be no reasonable question that the drug industry needs to be under stricter control; that its methods of advertising its wares to the doctor are wasteful, importunate, and often in bad taste; that different firms put out what is virtually the same drug under various trade names which merely leads to confusion; that the "authorities" quoted in the advertising of some drugs are often obscure individuals in countries not noted for the high standard of their practice of medicine writing in equally obscure journals; and that many drug firms make grossly inflated profits at the expense of our National Health Service. On the other hand, it must be remembered that some of the best drug firms have played a major part in medical progress. But they must constantly check their commercial instincts where these conflict (as they sometimes do) with your interests as the patient-consumer. To be fair about thalidomide, the fact is that nobody previously had seriously considered the possibility of a drug capable of causing deformity in the unborn child, and, if they had done, it is quite likely that the danger would still have been undiscovered, since only certain laboratory

animals respond to thalidomide in a similar way to man. The drug had been exhaustively tested by all ordinary methods before being put on the market, and for a number of years (during which, in Germany, it was on sale to the public without prescription because of its apparent safety), millions of people took it without any ill-effects either immediately or subsequently. Its terrible side-effects were, in fact, limited to those mothers who used it in early, not later, pregnancy, and in a lesser degree to a small proportion of adults who developed unpleasant, but not dangerous, symptoms of neuritis.

The taking of any effective drug is always a calculated risk. We have mentioned that the use of penicillin—a drug which is almost completely non-poisonous—may nevertheless cause other germs and fungi to multiply in the body with unpleasant results. This is because penicillin wipes out, not only the disease-producing germs it is being used to destroy, but the penicillin-sensitive harmless germs which hold the other potentially harmful germs at bay. Thus those who keep on sucking penicillin lozenges for a real or imaginary sore throat may develop a black tongue due to the spread of a fungus normally present but kept under control. Other antibiotics, described as "wide spectrum" because they wipe out an even greater variety of germs than penicillin, also kill the organisms responsible for the absorption and possibly the creation of vitamin B in the body, thus causing severe vitamin deficiency. Tranquillisers made by various firms vary from the wholly useless to the very useful, but both can have unpleasant side-effects. One type is prone to lead in a small number of cases to severe depression, others may lower the blood-pressure to a degree that causes fainting attacks, and serious blood and liver diseases are not unknown if not common. Both tranquillisers and the antihistamine drugs can cause some people to become extremely drowsy—an obvious danger if one drives a car or works on heights. Even aspirin causes gastric hæmorrhages which have sometimes been very severe and even lethal, particularly in those with peptic ulceration of the stomach and duodenum. Aspirin, one of the most useful and safest of drugs, should never be taken for an "upset stomach", or by people with known stomach trouble. Such patients should be warned that about 150 preparations including some hang-over remedies widely advertised for "upset stomach", contain large quantities of aspirin (acetyl salicylic acid).

None of this should deter the patient from being advised by a doctor he trusts to use whatever drugs are prescribed; it *should* deter him from putting emotional pressure on his doctor to obtain drugs unwillingly given. It is high time that we gave up the notion that no patient should leave the consulting-room without a prescription for some pill or potion; for something like 40 per cent. of patients simply require advice about the conduct of their life from their diet to their relationships with others rather than medicine of any kind. The housing shortage, a bullying boss, or a nagging mother-in-law cannot be removed by a tranquilliser—in fact, a tranquilliser, by making a man or woman feel better, may prevent them from constructively solving problems which exist in the real world. We should all learn to rely as little on drugs as possible: stop taking tranquillisers or pep pills when we are merely worried about something that any normal person would worry about, or because we are just "fed-up"; stop using antibiotics (which are badly needed elsewhere in the world) for trivial infections in which they are anyhow useless; stop swallowing vitamin pills which do not relieve tiredness and are merely wasted on this overfed nation; stop buying any patent medicine whatever. Modern drugs are potent and effective; they are a dagger to destroy the enemy of disease. But, like a dagger, those who play about with them incompetently and unnecessarily are liable to get badly hurt.

(4) New Methods in Surgery. Only a few years before the Second World War many surgeons were saying that surgery had reached its extreme limits. It was impossible, they believed, to improve on the delicate techniques then reached. But events have proved them wrong. Operations on the heart, for example, which would have been inconceivable a short time ago are now carried out daily—the heart can be opened and defects of the all-important valves made good. "Blue-Babies" or adults with a heart disease which might have led to their death in a few years are now cured by surgery, and it is possible during such operations to cut off all the blood from the heart by deflecting it through tubes to an artificial heart outside the body—a machine which pumps the blood round the body whilst the real heart is at rest.

This however, will be described in more detail later.

Then there are the new anæsthetics, such as Pentothal, which are injected into a vein in the arm instead of being breathed in through a mask, as were ether and chloroform or ethyl chloride. Pentothal is much safer, and avoids the unpleasant after-effects of vomiting and nausea, which usually followed the old type of anæsthetic. Most curious of all anæsthetists use the poison curare. used by South American Indians to poison their arrow-heads. Curare produces paralysis, but in small doses merely gives the degree of muscle relaxation which is so important to the surgeon when he is operating.

Lastly, we might mention the new techniques of plastic surgery. Thus large areas of skin which have been destroyed by severe burns can be replaced by shaving off thin layers from another part of the body. These do not need to cover completely the whole damaged area: small pieces are scattered over the wound and gradually grow together. Corneal disease (the cornea is part of the "window" of the eye, and when it becomes opaque the patient cannot see) is treated by removing the diseased cornea and replacing it by a cornea removed from a dead body, or sometimes from an eye which has had to be removed from a live patient for other reasons. There are, in fact, "cornea banks" where corneas are kept in refrigeration for future use, just as there are "blood banks" for use in blood transfusions. Other advances in surgery will be described elsewhere in the section.

(5) New Approaches in Social Medicine. Medicine has passed through many phases from the time when disease was regarded as a punishment from the gods or a sign of devil possession to the present era, when increasingly there is a tendency to look on society as the patient. Indeed, one commonly hears doctors and sociologists nowadays talking about "the sick society."

The early primitive stage came to an end—at least in one part of the world—when in Greece, five centuries before Christ, Hippocrates and others began to teach that all diseases were due to natural causes. But after the first ray of hope the outlook began to deteriorate when, during the Middle and Dark Ages (that is, from the fall of the Roman Empire right up to the fifteenth century), there was a return to the belief in devil possession and supernatural causes.

Eighteenth-century medicine in Europe was materialistic, regarding the body as a machine. It was founded upon a sort of pseudo-science—although, of course, there were always individual exceptions, physicians such as Sydenham in England, who, avoiding all theories, based their work on observation of the patient. This mechanistic approach persisted right through the nineteenth century, but medicine became more and more truly scientific, and the century saw the most rapid advances in the field ever known until our own times: the discovery of germs by Pasteur, of antiseptics to combat them by Lister, of vaccination by Jenner and anæsthetics by the American Wells and the Scot Simpson. The use of the microscope by Virchow, who was a German, brought great advances in the understanding of disease and Ehrlich, another German, conceived, as we have already seen, the idea of "magic bullets" which would attack the germs at the

root of a disease without harming the patient. But one of the greatest of all these great men is perhaps the least known. His name was Edwin Chadwick.

From the earliest period of recorded history human communities had been constantly ravaged by great plagues which swept over their lands year after year, killing untold millions. Such plagues are recorded in the Bible and other ancient books, but, when town life became more and more common, as during the Roman Empire and the Middle Ages in Europe, the overcrowded conditions were even more favourable to the spread of disease. The Black Death of 1348–9 wiped out almost half the population of Europe. But, even in the first quarter of the nineteenth century in London, tens of thousands died from typhus, typhoid, and smallpox—and not only these, for periodically cholera would be brought into the country by travellers from abroad.

In the face of these terrible visitations the individual physician was helpless. He could not treat each one of the many sick even had he known how, and Chadwick's claim to fame rests on the fact that he was the first man to think in terms of *social* control of diseases, by so dealing with their causes that they were prevented from arising at all. In order to wipe out typhoid and cholera, he argued, we must ensure clean water supplies; for these diseases are caused by germs carried in polluted water. In order to attack typhus and plague, one must get rid of the lice which carry the germs of typhus and the rat-fleas which carry the germs of plague (including, of course, the rats, which, in turn, carry the fleas).

In the past, some attempts had been made to segregate the sick to prevent the spread of disease —for example, in the case of leprosy (which, strangely enough, we now know to be less infectious than most germ-borne diseases). But segregating those who are sick with typhoid or cholera is of little use if others are still drinking polluted water, just as it is of little use segregating plague cases if rats with their infected fleas are allowed to run at large. So these early attempts met with little success, due to lack of understanding of how the infections were passed on.

Chadwick was born in a Lancashire farmhouse where the children were washed every day all over, and he ruthlessly drove an obsession with cleanliness into the heads of his countrymen until, later in the century, it was possible for the German philosopher Treitschke to tell his class in Berlin: "The English think soap is civilisation." Although this remark was meant cynically, there is little doubt that soap, if it is not civilisation in itself, has played a greater part in making civilisation possible than many more elaborate remedies. A population riddled with chronic infectious illness has neither the time nor the energy to apply to the arts or sciences, and soap did a great deal to reduce infection.

One of the first Public Health measures was introduced by Chadwick and others when they brought in legislation to purify the water supply of London. Previously, the citizens had used water from the Thames (they still do, but only after it has been filtered and sterilised at the waterworks!), and from filthy, refuse-laden ponds and springs. Later, Chadwick helped to found the Poor Law Commission, and produced a Report in 1842, the principal suggestions of which were: a municipal water supply for all towns; scientific drainage both in town and country; and an independent health service with large powers for dealing with those who endangered the lives of others by polluting water or causing nuisances. He also proposed a national service for interment of the dead; for in those days bodies often remained for days in the overcrowded homes of the poor without burial.

What has the twentieth century contributed to the concept of social health? Well, of course, there has been a great deal of legislation along the lines initiated by Chadwick to control disease, and a great many other measures have been introduced concerned with the idea of positive health—not merely preventing bad health, but trying to bring about the highest possible state of good health. Orange juice, milk, and good meals for schoolchildren have brought about a transformation in child health which has become apparent to the least observant. And the National Health Service is in the direct line of descent from early nineteenth-century legislation.

But in future years it is probable that the main achievement of the twentieth century in social medicine will prove to be its extension of the term "social health" to cover every aspect of community life, not only in such subjects as bodily health and its control of social means, but also such problems as mental illness, crime, delinquency, drug addiction, and so on. What we are now asking ourselves is: how far are these problems produced by society itself, and if this is the case, how far can we go in preventing them by social means?

Social medicine takes the view that these problems can never be dealt with solely by moralising and retribution, but only by dispassionately analysing causes and dealing with them. In this century we have developed a social conscience. Not always, it is true, a very well-informed social conscience, but at least this is a good beginning. There are organisations for dealing scientifically with delinquency, for dealing with problem children, for spreading knowledge about cancer in order to show people that it can be successfully treated if taken in time. The organisation known as "Alcoholics Anonymous" (11 Redcliffe Gardens, S.W.10; Tel. 01-352-5493) has, on the whole, been more successful in treating alcoholics by social means than have any of the individual medical methods. Mental illness is also treated by group methods, which, together with the new drugs, have revolutionised the position in mental hospitals. We can well say with John Donne, who died in 1631, that "no man is an island . . . every man's death diminisheth me; for I am involved in mankind." This is the attitude of twentieth-century social medicine.

Summary. Perhaps we can sum up our progress in the past hundred years more dramatically in terms of hard facts.

One hundred years ago, a surgical operation was never undertaken except under the gravest circumstances. There were no anæsthetics and no antiseptics, and the operation was carried out by a surgeon in a filthy tail-coat, stained with the congealed blood of countless operations (indeed the surgeons of that time took pride in the dirty condition of their coat as showing how much experience they had previously had). Germs and the part they play in producing disease were unknown, and Paul Ehrlich had not yet been born, so there were no "magic bullets" to attack syphilis, or sera for diphtheria and other diseases. The mentally ill were simply locked up with little treatment and subjected to such indignities as the strait-jacket and the padded cell; now they are given treatment which becomes more effective each year, the padded cell and strait-jacket have gone, and in the more progressive hospitals even the ward doors are not locked.

Only thirty years ago you would very likely have died if you had developed pneumonia, "childbed fever" after the birth of a child, meningitis, dysentery, typhoid, or tuberculosis. With such infections as blood-poisoning you would have had practically no chance at all. Today, the sulpha drugs and the antibiotics have changed all that. Syphilis and gonorrhœa were lifelong tragedies both to the patient and his family, but now they, too, can be conquered.

The National Health Service has brought the possibility of good treatment equally to all, and other bodies—some of them privately run—deal with alcoholism and neurosis, with rehabilitation of the mentally and physically ill, with spastics, birth control, and marriage guidance. It is up to us to see that all these facilities are used to the full by all who need them.

PART II. DISEASES ARRANGED ACCORDING EITHER TO THEIR CAUSE OR THE AREA OF THE BODY AFFECTED.

THE INFECTIOUS DISEASES
INTRODUCTION.

INFECTIOUS diseases are those which are caused by an invasion of the body by organisms from outside (the word "organism" simply means other living things, and we are using this word because, as will be seen later, it is not only what are known as "germs" which can cause infection). We know, too, that what is generally typical about this group is: (*a*) that the disease can be passed on from one person to another, and (*b*) that it is usually accompanied by a raised temperature or fever. Now (*a*), of course, is always true, because the definition of an infectious disease is one that can be passed on to others, but (*b*) is not always true, because a few infections produce little or no temperature, and also because it is possible to have a raised temperature (again in only a few cases) without any infection. For example, certain types of brain injury, tumour, or haemorrhage can produce a raised—or lowered—temperature, and so can the injection of some foreign substance such as milk into the muscles. This is known as "protein shock," and was at one time used in the treatment of certain illnesses. Finally, solutions of dead germs, such as the anti-typhoid vaccine given to protect troops during the War, may lead when injected to very high temperatures. But, by and large, we are entitled to suppose that the patient with a raised temperature is probably suffering from an infection.

Types of Infection.

As we have seen, it is not only germs which cause infections—so from now on we shall give germs their proper name of "bacteria." Here is a list of the chief offenders which are liable to attack our bodies: bacteria, spirochætes, viruses, fungi, amœbæ, worms and other parasites. Of these, bacteria and viruses are by far the most important, but let us look at them all more closely.

Bacteria are tiny living things which can be seen only under a fairly powerful microscope. Some are grouped like bunches of grapes (staphylococci) or in strings or chains (streptococci). They are given these names because "staphylos" is the Greek word for a bunch of grapes, and "streptos" means a chain. Yet others are comma-shaped (such as the cholera vibrio), or shaped like a drumstick—a rod with a small knob at the end (the tetanus bacillus, which causes lockjaw).

It would be a mistake to think that all bacteria are harmful; for without some species we could not survive for long. Bacteriologists divide them according to their behaviour in the human body into three groups: saprophytic, parasitic or pathogenic, and symbiotic. The *saprophytic* organisms are the bacteria normally found in the skin, mouth, and intestines; they do us neither harm nor good. The *parasitic*, or as they are more usually called, pathogenic (*i.e.*, disease-producing) organisms, are the harmful ones with which we are naturally more concerned. Lastly, there are the *symbiotic* organisms, which, whilst taking something from the body, give something in return. For example, cattle would not be able to digest the cellulose of the grass they eat were it not for helpful bacteria in the lower parts of the intestines, and there are certain bacteria in the large intestine of man which build up vitamin B2.

Bacteria have two peculiar characteristics: each reproduces by splitting into two separate individuals as often as every twenty minutes in favourable circumstances like an open wound. If no bacterium were destroyed, one individual could produce a mass of bacteria larger than the whole world in a matter of a few weeks (since each of the offspring also divides into two, which in turn divide again—the progression goes: one gives birth to two, these two to four, the four to eight, eight to sixteen, sixteen to thirty-two, and so on—you will see, if you work it out, that in a short period the figure becomes astronomical). Fortunately, many bacteria have accidents, so for the present the world is safe! The other curious thing about bacteria is that, barring accidents, they are potentially immortal. Under ideal conditions in which no bacteria were killed, none would die; for a bacterium there is no death from old age, no corpse except when it is actively destroyed. It simply goes on dividing, dividing, and subdividing for ever.

How, then, are bacteria destroyed? Briefly, the answer is that most are destroyed by the natural defences of the body of whatever host they are preying on; others are destroyed by antiseptics and the new drugs; and many are destroyed when they are excreted from the body in the sputum or through the bowels and land in places where they are dried up and cannot survive—although some bacteria in such circumstances can form what are called "spores," rather like the seed of plants, so making it possible for them to survive in a state of suspended animation for months on end until picked up accidentally by another unfortunate host. Finally, bacteria, in addition to all these possibilities, face another danger: they may themselves develop disease. This disease is caused by even more minute organisms known as bacteriophages (viruses which affect bacteria), discovered by F. W. Twort in 1915. Attack by bacteriophage causes whole groups of bacteria (known as "colonies") to disintegrate and become harmless.

Although bacteriophage has been used in the treatment of some diseases in human beings, this method has now been largely given up, since the new drugs are infinitely more effective.

Spirochaetes. Spirochætes, like bacteria, are minute organisms, but differ in being shaped somewhat like a corkscrew and in being able to move (which many bacteria cannot do). Their progress is produced by a sideways wriggling motion. The two main diseases caused by spirochætes are syphilis and spirochætal jaundice. Spirochætal jaundice is carried by rats, and is common in those who work in mines. It is now rare in Britain, but still occurs in Japan, Egypt, and Malaya; the infection is passed through the skin where the excreta of infected rats mingles with water on damp ground in the mine where miners kneel. Infection may also occur through eating infected food.

Viruses. Unlike bacteria, viruses are too small to be seen under an ordinary microscope. They can, however, be photographed in some cases under an electron microscope, which uses a magnetic field instead of a glass lens and a stream of electrons in place of a beam of light. Viruses cause such diseases as typhus, measles, mumps, poliomyelitis, smallpox, and chickenpox—not to mention such plant and animal diseases as tobacco mosaic disease and foot-and-mouth disease, which often have serious economic consequences. Other virus diseases are psittacosis (an infection of parrots and similar birds which can be transmitted to Man), swine fever in pigs, influenza in Man, and myxomatosis in rabbits. They also cause, it is believed, the common cold.

The main characteristics of viruses are, first, that they can only grow in living cells—unlike bacteria, which readily grow in the laboratory on plates containing a jelly made from meat broth, gelatin, milk, and other delicacies. The scientist, therefore, must keep them in portions of living tissue kept alive outside the body. Secondly, they are so small that they pass through the pores of the finest filter. Thirdly, a first attack usually produces immunity for life. Second attacks of the common virus diseases mentioned above are very rare; but unfortunately, this rule does not apply to influenza or the common cold. Fourthly, there is reason to believe that viruses represent an extraordinary intermediate stage between the living and non-living; they can, for instance, be produced in crystalline form and yet are just as dangerous when "thawed out." Lastly, the virus diseases have proved for the most part to be little affected by the new antibiotics and other drugs, although vaccination in smallpox and the injection of sera from infected patients in other infections may give immunity for longer or shorter periods.

The two great practical problems that doctors face with viruses are: (i) many viruses are unknown because of the difficulty of growing them outside the body in suitable tissue culture. They cannot therefore be conveniently identified in specimens from the patient, as bacteria can; and (ii) they are unaffected by antibiotics like penicillin. It has been a great step forward to grow viruses artificially in tissue culture, in which they are identified indirectly by the effects they have on the cultured *cells*. But since we do not know exactly how to grow some viruses (like those of infective hepatitis) they have still not been seen.

When we recover from a viral illness like chickenpox, we probably do so by producing virus-killing substances inside our own cells. Scientists are currently searching for these substances in case they can be used, like penicillin, to cure viral disease.

Fungi. Some infections are caused by fungi—that is to say organisms belonging to the same group as moulds, mushrooms, and toadstools. Penicillin and some other antibiotics are produced from moulds, so, as in the case of bacteria, some fungi are helpful; they even help to destroy each other, as bacteria do. For example actinomyces, which can cause infection of the jaw and other tissues, is destroyed by other tissues.

Most fungal infections are trivial and limited to the skin. But, although trivial, they can be unsightly and uncomfortable. Ringworm of the scalp, dhobie itch—an infection of the groin spread by infected underclothing—and so-called "athlete's foot" are caused by a fungus.

Amœbae. Amœbæ are small, single-cell organisms, the largest of which (a harmless type found in stagnant ponds in Britain and elsewhere) is just visible to the naked eye. It is about the size of the head of a pin. Amœbæ move, in the species which are capable of moving, by pushing forward a part of the cell in the appropriate direction and causing the rest to flow into the advancing portion. Like bacteria, they reproduce by dividing into halves, each of which becomes a new amœba.

The main human disease caused by amœbæ is amœbic dysentery (not to be confused with bacillary dysentery).

Parasites. These may live on the skin like lice (which can carry typhus) or fleas (carriers of plague), or the parasites of scabies which burrow into the skin, or they may live part of their time in the blood or other tissues, like malaria. They often have complicated life-cycles involving other hosts (like mosquitoes) at certain stages of development.

Worms. Worms are intestinal parasites, but the only common types found in Britain are threadworms, the tiny thread-like worms which cause irritability and itching in the skin of children, less often in adults; round-worms, somewhat resembling the ordinary garden earthworm, which seldom lead to symptoms; and tapeworms, which may reach a length of 10 or even 20 ft. Many parasitic worms (like parasites elsewhere) lead a double life—they spend part of their life in the human intestine and the other part in the muscles of another animal. The tapeworm, for example, whilst in the human intestine, lays eggs which pass out of the body in the excreta, and are then swallowed by pigs, especially in those parts of the world where human excreta are used as manure in the fields. In the pig, the eggs form cysts in the muscles—meat infected in this way is known as "measly pork"—and when, in turn, the meat is eaten by man, the process in the intestine begins all over again.

Less common types, from our point of view, are the Russian tape-worm (which, as befits a Russian, grows to nearly 30 ft.!); this type is spread by caviare or undercooked infected fish. The small, leaf-shaped liver fluke, lays eggs which are passed into canals or pools in tropical countries in the urine of infected people, hatch out and enter a water snail, and finally leave the snail in the form of small parasites which pierce the skin of bathers, whence they pass to the liver and subsequently the bladder and rectum. This is a serious condition, as is also filariasis (another tropical disease), for which, unlike bilharzia—caused by the liver fluke—no cure is known. The tropical disease known as loa-loa is caused by a variety of filaria.

How the Infection is Spread.

Infection is spread in many ways, some of which have already been mentioned. In the common fevers found in Europe and elsewhere one of the most frequent ways is by *droplet infection*—that is to say, by minute drops carrying the germs which are coughed or sneezed into the air by someone already suffering from the disease. Such droplets can be projected into the air for 10 ft. or more, and when breathed in by someone within range infection may result. Next commonest mode of spread is perhaps by *infected food, water*, and the dirty hands of those who prepare food: cholera, dysentery, food-poisoning, and typhoid are spread in this way. Spread by *direct contact* is found in the venereal diseases (usually, but not always, spread by sexual intercourse with someone who already has the disease), and, of course, lice, fleas, and other parasites, including the scabies mite, are spread by contact with the infested individual—or sometimes with his clothes or bed linen. Spread through an *intermediary host*, whether it be lice, fleas, or mosquitoes carrying infection, or the various means adopted by worms, has already been described above, so no more need be said. Lastly, the infection may result from *bacteria already within the body*; for example, the bacillus coli which lives in the large intestine is there harmless, but if it gets into the bladder or the ureters (the tubes leading from kidney to bladder) a quite unpleasant result may follow in the form of cystitis or pyelitis.

How the Body Deals with Infection.

The body has many mechanisms of defence against intruders, but suffice it to say here that there are two main ones. First, substances known as antibodies and antitoxins are produced in the blood—the antitoxins to neutralise the poisons produced by the invaders, the antibodies to render them helpless, for example, by causing them to clump together so that they can more easily be dealt with by the second defence mechanism. This second mechanism is provided by the white cells in the blood, some of which (the phagocytes) act like amœbæ and swallow up and destroy the germs. Antibodies and antitoxins can be transferred from one individual to another and are used in medicine both to prevent infection and to cure it. This is known as immunisation, and can be active or passive. Active immunisation is produced by injecting either a solution of dead bacteria, as in the case of anti-typhoid injections, or by injecting live, but weakened, strains of the organism, as in the case of smallpox vaccination. In both cases the body is stimulated to produce its own immune substances. Passive immunisation is used either for people who have been in recent contact with infection or who are already ill, and in this case the antitoxins produced in another person who has had the illness are injected in the form of serum—*i.e.*, the liquid part of the blood without the blood cells. All these natural defences are inefficient in the ill, the underfed, the very young, and the very old.

Antiseptics.

We have already discussed the other ways in which bacteria are destroyed and now need only make brief mention of antiseptics, and antibiotics. The earliest antiseptic was carbolic acid, used by Lister in his operating-theatre in the form of a fine spray directed throughout the operation on the wound, or sometimes in the form of steam from a kettle containing a solution of carbolic. But carbolic is dangerous, and since Lister's time many more useful antiseptics have been discovered. Acriflavine, thymol, and other old favourites have been discarded too. The various forms of carbolic are still used to disinfect drains, but, to tell the truth, the use of antiseptics nowadays is very limited. In surgery the *antiseptic* method has given way to the *aseptic* method—instead of fighting sepsis we see to it

that no possibility of sepsis is present before operating: all instruments, the surgeons' and nurses' hands, the skin, are sterilised—the instruments by boiling, the dressings by dry heat, the hands by soap and water, and almost the only antiseptic used is to clean the patient's skin in the area to be operated on.

Antiseptics are used as first-aid treatment for cuts and wounds, but should be applied only once as a general rule—that is, when the wound is first received. The trouble with antiseptics is that as well as killing germs they also kill the surrounding tissues, which antibiotics never do.

Antiseptic sprays to purify the air of a room or to destroy germs lurking in the dust on the sick-room floor—or any other floor—are practically useless. To quote the *British Medical Journal*: "There is no good scientific evidence that any of the chemical air-disinfectants can control the spread of infection in places such as schools, offices, or cinemas. Nor is there good evidence that any substantial effect on the spread of illness can be obtained by disinfection of dust."

Neither is there any good reason to believe that mouth-washes and gargles have any effect other than making the mouth feel fresher and (temporarily) removing mouth odour—by covering it up with the scent of the antiseptic. Mouth-washes are in contact with the bacteria for far too short a time to have any damaging result, and, in the case of tonsillitis and other diseases, all the important bacteria are hidden far out of any danger from gargles.

Antibiotics.

The antibiotics—penicillin, streptomycin, erythromycin, terramycin, aureomycin, and chloramphenicol—have already been dealt with, and only two important practical points need to be mentioned. These are that although most of such drugs are entirely safe under ordinary conditions, it is extremely dangerous for the layman to use them without medical guidance. If, for example, people get into the undesirable habit of sucking penicillin lozenges for sore throat and keep on doing this every time the sore throat returns, they may become sensitised to penicillin so that, when they become really ill—say, with pneumonia—the serious illness no longer responds to the drug. Or the same habit may make them allergic or hypersensitive to penicillin, and an injection given later may have serious and even fatal results.

Doctors no longer use the lozenges anyway, because of this danger and another one which is that excessive use of antibiotics may kill not only the dangerous bacteria, but also the ones which are helpful to the body. When this happens, other types of organism which are not affected by antibiotics will multiply in the absence of the bacteria which normally keep them under control. Thus chloramphenicol or aureomycin, by killing useful germs in the large intestine, may cause vitamin B deficiency, and when the non-sensitive organisms have their natural enemies removed they may step in and multiply, causing inflammation of the mouth, diarrhœa, and occasionally a fatal bowel infection. Chloramphenicol is too dangerous for general use.

General Treatment of Fevers.

Fevers are ordinarily heralded in by a rise in temperature which is noticeable either by a flushed face or by alternate sensations of heat and cold. A patient with a high temperature may have shivering attacks known as "rigors." Tell the doctor.

A high temperature does not necessarily (especially in a child) mean that the trouble is serious but the lay person should always treat it as such and certainly call a doctor if the patient is a child or an elderly person.

Even the trained physician finds it difficult to tell one fever from another in the early days; for most of the common fevers begin in more or less the same way. It is only when a rash or some other more definite sign becomes evident that a certain diagnosis can be made, and these may not show themselves until the patient has been feeling "run-down" and fevered for some days. Incidentally, although a clinical thermometer is a very useful thing when properly used, many a doctor must feel that, in unskilled hands, it is a menace. The "fussy" type of mother who is constantly taking her child's temperature whenever it looks in the slightest degree different from usual (probably it is simply feeling justifiably bored with its parents), not only causes anxiety to herself but also gives the habit of anxiety to her child. The child is made to feel that the world is a dangerous place, full of germs and all sorts of causes for fear—as indeed it is, but one needs a sense of proportion, and other dangers which we think much less about are at least as frightening and twice as deadly as most germs. Whatever you do, don't get the thermometer habit; your child, so far as fevers are concerned, is a good deal tougher than you.

Briefly, then, the way to treat a fever in the early stages before the doctor comes, and before one knows exactly what is wrong, is as follows:

(1) Put the patient to bed.

(2) Give little, and easily digested, food; if the patient wants none, give none.

(3) Give plenty to drink—the proprietary preparations containing lemonade and glucose are excellent, but water, weak tea with sugar, or home-made lemonade with squeezed-out lemon juice and sugar, whichever the patient likes best, are at least as good.

(4) Aspirin is useful to relieve headache or other pains and will reduce fever for two or three hours. But it will cure nothing. The patient will be more comfortable, but his illness will not be cured by aspirin except in certain very special cases. Soluble aspirin is best. Do not have special children's aspirins in the house. They are often nicely flavoured, the children are tempted to eat them like sweets, and there have been serious cases of poisoning. For small children, use suitably small quantities of ordinary adult soluble aspirin, having checked the dose with your doctor. Other methods of cooling seriously fevered patients such as bathing, tepid sponging, etc., are strictly for the doctor to prescribe. A patient as hot as that should be in a doctor's hands anyway.

THE INFECTIOUS FEVERS.

The remarks made above apply to the management of *any* fever, and we are now going to discuss particular infectious diseases, beginning with the common childhood fevers, then passing on to less common ones, tropical diseases, and worm and parasitic infestations.

The common infectious fevers are caused by bacteria or viruses, and it is useful to know the meaning of the following terms: *incubation period* is the time which elapses between being infected and developing symptoms; *prodromal period* is the time which elapses between the end of the incubation period and the appearance of a rash; *quarantine period*, the maximum time during which a person who has been in contact with the infection may develop the disease—it is usually two days more than the incubation period; *isolation period*, the time a patient is supposed to be isolated.

Views regarding the common infectious fevers have changed a good deal in recent years. Disinfection of rooms is now regarded as almost useless, and more cases are treated at home. Quarantine in the case of the common fevers is thought by a good many doctors to be a waste of time, since all it can do is to postpone infection from early childhood to early adult life, when it is likely to be more serious. For it is a characteristic of these fevers that they affect the adult much more violently than they do the child. However, on this, and all other points, you will have to be guided by the opinion of your family doctor.

Virus Diseases.

First, we shall take the common virus diseases, measles, chickenpox, and rubella or German

measles, then the other virus diseases, mumps, infective hepatitis, virus pneumonia, and some less common conditions which do not always produce a typical rash as in the case of the first three.

In nearly all of these fevers there is a long incubation period, and one infection gives immunity for life.

Measles. The incubation period is 10–11 days. The first sign is the appearance of symptoms rather like a severe cold. The eyes become red, and exposure to light is unpleasant, the nose runs, the throat becomes inflamed, and a dry, harsh cough develops. There may be headache and the temperature rises to 102° or more. Usually the patient is a child, and especially typical is the development of so-called Koplik's spots, which are small, bluish-white, raised spots seen on the inside of the cheek at the back of the mouth. The rash begins on the fourth day of the prodomal period, *i.e.*, 14 days after the initial infection. It shows on the forehead and behind the ears, spreading within a day downwards over the whole body; in another two days it starts to disappear, but often leaves behind a sort of brownish staining which may last for one to two weeks.

Measles can be serious, especially in very young children because of its complications, such as bronchopneumonia and infection of the ear, which can now be treated with antibiotics. These drugs have no effect on the measles virus, but only on the secondarily invading bacteria which have invaded the lungs and ear during the illness. The illness can be attenuated or lessened by injection of antibodies (gamma globulin) from an immune adult, and this is often worth while in the very young.

Rubella or German Measles. Incubation period 14–19 days. A mild fever, similar to measles except that the rash is usually the first sign that anything is wrong, and the temperature is rarely above 100°. The eyes may be pink, and there are enlarged glands at the back of the neck. The rash disappears completely in thirty-six hours. There are no complications.

German measles, in itself, is harmless, but if a woman gets the disease in the early months of pregnancy malformations in the child may appear at birth. Hence some doctors believe that girls particularly should have the opportunity of contracting German measles before they grow up. There is no special treatment, except the general rules for fevers given above.

Chickenpox. Incubation period 14–15 days, but may be more variable. In children chickenpox is a mild fever which begins with the appearance of tiny blisters on the chest and back. These later spread outwards to the legs, arms and face, and cause itching. Treatment is the general one for fevers already described. Calamine lotion or dusting powder will be helpful for the irritation, and the child's nails should be cut short to prevent scratching and infection of the spots. Whereas children are usually little bothered by chickenpox, young adults may be much more drastically affected—a temperature of 104° is not uncommon, and there may be severe headache.

Mumps. Incubation period 17–18 days. Everyone knows the typical appearance of the patient with mumps—the swelling in the salivary glands in front of the ears which makes the face look full. This causes pain later on, and it may be difficult to open the mouth. Temperature is not usually high (about 101°). Although uncomfortable, mumps is rarely dangerous, but orchitis—swelling of the testicles—is sometimes a complication. Fluid diet should be given if eating is painful, with mouth-washes, and rest in bed.

Infective Hepatitis. "Hepatitis" means inflammation of the liver, and infective hepatitis, which is much the commonest cause of jaundice in young adults, is a virus infection of the liver. The main symptoms are fever, followed by jaundice, which is first noticed in the whites of the eyes as yellow staining, then in the skin. The urine becomes coloured also, and this is most easily noticed if, on shaking in a bottle, the froth shows coloration. If the froth remains white, no jaundice is present. Treatment is a matter for the doctor, but great care should be taken both by the patient and those in contact with him, to wash the hands thoroughly after urinating or defæcating, after handling utensils from the sickroom, and both before and after eating; for the disease is very infectious.

Virus Pneumonia. Pneumonia is usually caused by bacteria, and when we speak of pneumonia, that is the type we ordinarily refer to. Virus pneumonia is known by doctors as "pneumonitis," and is believed to be closely related to influenza. There is no specific treatment so far, and since diagnosis is a specialist matter, little more need be said except that the symptoms in general resemble those of ordinary pneumonia. Psittacosis, another virus disease, can also lead to pneumonia, and although there is no specific treatment for virus infections of the lungs, it is always worth while trying the antibiotics or sulpha drugs in view of the possibility that the lung condition may be caused by a secondary invasion by bacteria.

Influenza. While serious epidemics of influenza take the form of a very dramatic and often fatal disease—for example, the epidemic of "Spanish 'flu" which followed the First World War killed more people than the actual fighting—the milder type more usually seen is difficult to distinguish from the common cold. In fact, many people who complain of "a dose of the 'flu" are suffering from simple colds.

However, a sudden onset, aching in the muscles of the back and legs, and redness of the eyes, would suggest influenza, and especially typical is the depression and weakness which follow influenza but not a cold. The measures suggested above for the general treatment of fever should be applied; but the depression and weakness which follow influenza may need special treatment by the doctor.

Colds. Although everyone thinks he, or she, knows what a "cold" is, the issue is not so simple; for the symptoms of fever, running nose, and a run-down, "headachy" feeling are found in many illnesses. They may be observed, as we have seen, in the early stages of measles before the arrival of the rash, or in a number of other fevers, such as whooping cough. Mild attacks of influenza (see above) may resemble the common cold, and blocking of the nose with discharge and fever may be due to sinusitis—although here there is usually pain above, between, or below the eyes. Colds can be caused by any one of thirty different viruses known as "rhinoviruses" as well as by others which cause influenza, or infect glands (adenoviruses). This is why a single cold does not confer immunity on the sufferer. It is probable that you will not catch a cold from the same virus, at least for the rest of the year, but there are all those others waiting to infect you with other colds in buses, tubes, and other crowded places. Like all infections, do not forget that the best way to avoid them is to keep generally well, and in a good nutritional state. Do not spend money on injections or other vaccines. They do not work, probably because of the multiplicity of viruses involved. It is unlikely that adding vitamins or mineral supplements to normal diet will do any good at all provided you are eating sensibly. The vogue for prophylactic or therapeutic treatment of colds with massive doses of vitamin C has recently received much attention from scientists attempting, with some success, to prove the effect by controlled clinical trial and to find a rational basis for its use. *See* **Vitamin C and the Common Cold, Part III.**

Poliomyelitis. "Polio," or infantile paralysis as it used to be called, is a virus infection of the motor nerves—the nerves of movement—at the point where they leave the spinal cord. Fortunately, all the nerves are never affected, but only a few controlling one or more muscle groups.

If these groups happen to be the ones controlling breathing or swallowing (which, fortunately, is not very common) the results may be serious, but ordinarily the muscles affected are those of the legs or arms. Poliomyelitis is almost as common now in adults as in children. Usually it occurs in small epidemics after hot weather, that is in Summer or Autumn, and it often seems to strike at fairly healthy normal people. This, however, is not because healthy people are specially prone as such, but because those living under less hygienic conditions are more likely to have developed immunity. In point of fact, the majority of cases of polio are so mild that they are never discovered at all, and paralysis does not develop; such people are specially dangerous, precisely because they pass unnoticed and spread the disease to others.

Like many other infections, polio begins with sore throat, fever, and sometimes vomiting five to ten days after contact. There may be severe headache and rigidity of the neck muscles. Paralysis is noted about the second or third day after this, and is usually at its maximum from the start, although this is not always the case. This stage lasts two or three weeks, by which time the temperature is down and the paralysis greatly improved, although further improvement may go on up to eighteen months after the acute stage.

This is another disease which has been dramatically reduced and even wiped out in many areas by the widespread use of vaccine. However, when the illness is already present attention is directed to relief of discomfort, resting and splinting the affected limbs, and preventing spread of infection to others. The Kenny method, devised by Nurse Kenny, and much publicised as a means of reducing permanent paralysis, is not believed by most doctors to be any improvement upon orthodox methods. The use of the iron lung is restricted to cases where the muscles controlling breathing are attacked, and any permanent paralysis of the limbs can often be helped by surgical operation.

Encephalitis. This is an infection of the brain caused by a virus, first noted in Vienna in 1916. There was an epidemic in London in 1918, but it is not very common today.

Smallpox. Smallpox was once common in Western Europe, and, as late as the early nineteenth century, was not unknown in Britain. Now, since the introduction of vaccination, it is comparatively rare in industrialised countries, although minor epidemics have occurred here recently. Jenner, who introduced vaccination, noted that dairy-maids who had suffered from the mild disease known as "cow-pox," contracted from the udders of infected cows, and transmitted to the hand of the dairy-maid, did not develop smallpox. In fact, cow-pox is a mild form of smallpox modified by transmission through cattle. Vaccination should be carried out at the age of three months, and repeated at the ages of seven, fourteen, and twenty-one years—also at any time when an epidemic occurs, or when travelling to any part of the world where smallpox is prevalent, or where immigration laws stipulate that it must be done. Many countries insist on an international certificate of recent vaccination before landing. Your family doctor will make out the certificate (he is entitled to charge you for it) and your local Medical Officer of Health will countersign it. Smallpox is one of the diseases which can very readily be spread from countries where it is prevalent because of the great increase in numbers of people travelling about the world by air.

Smallpox attacks people of all ages and is carried by excreta and droplet infection, but particularly by the dried scales on the skins of convalescent patients; it is now most common in the tropics.

Smallpox is similar in many ways to chickenpox. Typical cases are easy for the qualified doctor to distinguish from one another, but one of the difficulties of vaccination (as with Typhoid, and other artificially conferred immunities) is that the typical signs are often modified. Differential diagnosis is a job for the expert, and if your own doctor is in any doubt, he will consult with the local health authorities. The disease begins with shivering, headache, and backache, and the temperature is raised to 102–104°. On the third day a rash appears, which turns into small blisters on the sixth day, and the blisters become filled with pus by the ninth day. On the twelfth day they burst and form crusts. Unlike chickenpox, in which the rash starts in the middle of the body and works towards the outer parts, smallpox produces a rash which begins in the scalp, forehead, wrists, and feet and then moves towards the middle.

Smallpox is a serious disease, and the result depends largely upon whether the patient has been vaccinated within seven years of the attack. Contacts should be vaccinated and kept under observation for sixteen days; the patient must be isolated until all the scabs have separated and the skin healed. An effective drug has recently been announced.

Glandular Fever. This is sometimes called infective mononucleosis, since one of its features is an increase in certain mononuclear white cells and an alteration in their appearance. Another feature is an apparent infectivity. Beyond this the disease is a great mystery, and although it is probably caused by a virus, it may even be related to other (malignant) diseases of white cells. This one, however, is not dangerous although it often causes a lot of trouble by dragging on for many weeks. The main symptoms are fever, enlargement of lymph glands and sore throat. The patient feels very debilitated and often very depressed. Diagnosis is often very difficult, but there is a blood test known as the "Paul-Bunnell" test which is almost specific for the disease. The patient is usually presented as a case known to doctors as "P.U.O.," meaning Pyrexia (fever) of Unknown Origin. He has often been treated with several antibiotics, one after another, without effect, because the causal agent is not affected by these drugs. He is only very mildly infective, and it is unusual to insist on isolation or quarantine.

Typhus. This disease used to be known as "jail fever," because it was frequent in prisons; but overcrowding, poverty, and bad hygienic surroundings anywhere are suitable conditions for epidemics of typhus. Improved conditions in industrialised countries have made it unusual, since typhus is carried from one person to another by infected body lice. It is due to the organism *Rickettsia prowazekii*, which displays both bacterial and viral characteristics.

Typhus comes on suddenly with a rise in temperature of about 102°, but within four days it may be as high as 107°. There may, or may not, be a rash at this time, and in the second week, when the temperature is at its highest, there is delirium, weakness, and a feeble pulse. The typical typhus rash appears about the fifth day as reddish blotches on the chest, abdomen, and wrists.

Typhus is, needless to say, very serious but responds to such modern antibiotics as chloramphenicol, aureomycin, and terramycin. Preventive measures are directed towards destroying all lice with D.D.T.

Rabies. Finally, we shall deal very briefly with a number of less common virus diseases, beginning, as is appropriate, with *hydrophobia or rabies*, since it was in this infection that the great French scientist Louis Pasteur (1822–95) showed the possibility of prevention by vaccination. Unlike Jenner, with his ready-made cowpox virus, which we have seen to be the virus of smallpox weakened by natural passage through cows, Pasteur had to weaken the rabies virus by passing it through rabbits. The rabbits were infected, and after death the spinal cord was dried and powdered, a solution passed through another rabbit, and so on until the virus was sufficiently weakened.

Rabies is spread by the bite of infected animals, usually dogs, cats, or wolves, who are driven mad by the disease; in Trinidad, however, it has been spread by vampire bats. Those who are bitten usually show no symptoms for six weeks or more,

but sooner or later convulsions and delirium arise, which within four to five days are fatal.

There is no cure once the symptoms have developed, but Pasteur's serum, if given soon after the bite, prevents illness in the vast majority of cases—the sooner after the bite, the better the outlook. Dogs should be muzzled in areas where the disease is common, but quarantining imported dogs has made the infection almost unknown here.

Psittacosis. This is another virus disease which is of interest mainly in that it is spread by birds of the parrot group, such as parrots, lovebirds, macaws, and the rest. It occasionally occurs here in people who have been in contact with birds of this type, and is serious both to the bird and its owner. As in the case of rabies, quarantine regulations have greatly reduced the likelihood of infection in Britain.

The symptoms of psittacosis are fever, cough, and bronchitis. The disease is especially dangerous to old people, but it responds to the same antibiotics as typhus.

Sandfly Fever, or phlebotomus fever, *Dengue*, or breakbone fever, and *Trench Fever* are all somewhat similar conditions in that they resemble influenza and are rarely fatal. They are all due to viruses, spread in the first case by sandflies in tropical climates; in the second by mosquitoes in tropical climates; and in the third by lice in temperate climates. They are all typical "soldiers' diseases"; the first two were common in the Middle East and Far East during the last War, the third during the First World War in France.

Yellow Fever. Of all the virus diseases, only four can be prevented by vaccination—smallpox, hydrophobia, yellow fever, and poliomyelitis. Yellow fever is carried by a mosquito known as Stegomyia, common in South and Central America and in African ports. For its spread, it therefore needs: a hot climate, the stegomyia mosquito, and an infected person.

In 1898 the United States was at war with Spain in Central America, where yellow fever was a serious problem. Following this war the United States, by this time acutely aware of this terrible disease, asked a Dr. G. E. Waring to deal with it in Havana, where it was rife. But Waring died of yellow fever, as had many millions before him, without knowing its cause, and it was left to Walter Reed, who died in 1902, to prove the connection between the mosquito and yellow fever. By a vigorous war on the mosquito, the disease has been eradicated from Havana and the West Indian islands, and Reed's discovery made possible the building of the Panama Canal (Ferdinand de Lesseps, the builder of the Suez Canal, had made a similar attempt in Panama, but had been beaten, amongst other factors, by yellow fever).

In yellow fever there is a sudden high temperature, aching of limbs and head, jaundice, and black vomit; the pulse-rate falls as the fever rises. Previous vaccination seems to be preventive if undertaken in time.

Conclusion.

All these virus diseases have this in common: that for many there is no specific cure, although smallpox, rabies, yellow fever, and poliomyelitis can be prevented by vaccination, or by the social control of the creatures carrying the virus. Some of the larger viruses (psittacosis, whooping cough) are destroyed by certain antibiotics. There is usually a long incubation period. Finally the question will sometimes arise of protecting some people from German measles or measles with gamma globulin containing another person's antibodies to the disease. This may be considered for measles in very young patients or to protect the fœtus in pregnant mothers in contact with German measles.

Bacterial Diseases.

Bacterial diseases differ from virus infections in a number of respects: their incubation period tends to be shorter; having the disease once does not often confer lifelong protection; and unlike virus diseases, most bacterial diseases respond to one of the antibiotics or sulphonamides. In many cases it is possible to inoculate against the disease to prevent it occurring, as we have seen is possible with only a few of the virus diseases.

Scarlet Fever and Other Streptococcal Infections. In the days, not so long ago, before the arrival of chemotherapy (sulphonamides) and antibiotics, streptococci were very much feared and even caused a high mortality, particularly in such susceptible groups as children, and mothers and babies in maternity hospitals. They are still taken very seriously in the latter and rightly so, although one wonders how much of the mystique is simply a hang over from the days, thirty years ago, when many mothers died from "childbed fever." All signs of infection, such as fever, during the puerperium (the period following childbirth) must be promptly dealt with by a doctor, and only occasionally now is there real cause for anxiety provided treatment is prompt and rigorous.

Scarlet fever is much less common and very much less serious an illness than it used to be, partly because of the effective treatments available today, but also because of a definite but unexplained reduction in its severity. Perhaps the streptococcus has changed, and certainly the improved physical condition of people who are now much better fed and housed than they were, has helped to ward off the terrors of this disease as of so many other infections. The classical picture of signs and symptoms is now so rarely seen that it will not be further described.

The importance of streptococcal infections has shifted from the initial infection, such as a sore throat, to some serious conditions which occasionally arise as a result of some form of delayed sensitivity to the bacteria. Acute rheumatism or rheumatic fever (not to be confused with ordinary aches and pains nor with rheumatoid arthritis) occasionally arise in people who have had a sore throat a few weeks before. Since the streptococcus is not the direct cause of the damage which may consequently occur in the heart or kidney, the antibiotics are no answer except sometimes to keep off further streptococcal invasions.

Diphtheria. This used to be an extremely serious disease, but immunisation has made it almost unknown; it is important, therefore, that all children should be immunised. There are many modern and up-to-date doctors who have qualified since the war who have never seen a case because it has become so rare, and in spite of the propaganda of certain ill-informed people this saving of children's lives is entirely the result of nationwide inoculation during the war and since. The following description is of historic interest only, and will remain so if a high level of inoculation is kept up by parents.

In a typical case of diphtheria the incubation period is about three days; the patient is a child who becomes ill and pale-looking (*i.e.*, the onset is not sudden, as in many fevers, but insidious); the temperature is only slightly raised to, perhaps, 99° or 101°, and although there may be no complaint of sore throat, examination will reveal inflammation with—and this is typical of diphtheria—a grey membrane spread over the tonsils, the palate, and the back of the mouth generally. The diphtheria germ does not spread within the body. It stays at the place where it entered (in this case the throat) and sends its toxins throughout the body.

Even after the acute phase is over the patient must not be allowed to walk, because the diphtheria toxin is particularly poisonous to the heart. The ordinary rule is at least one or two months in bed.

Diphtheria also occurs in the larynx—in pre-inoculation days many children choked to death with this form of the infection; in the nose; and, although this is not generally known, wounds can be infected. The so-called "Desert sores" of the North African campaign seem to have been caused by diphtheria-like organisms.

Diphtheria may lead to paralysis of the throat, with difficulty in speaking or swallowing, and paralysis of the eyes or limbs; these are due to

neuritis caused by the influence of the toxin on the nerves.

Whooping Cough. For many years whooping cough has been regarded merely as a bother to the patient and a nuisance to others, as, in fact, a trivial disease. Unfortunately, this is not so; because statistics show that it causes more deaths than polio, diphtheria, scarlet fever, and measles all put together.

Whooping cough begins in a child as an ordinary cold with cough and slight fever, and this stage lasts for a week or ten days. Then the "paroxysmal stage" begins as a series of coughs following in rapid succession, during which time the patient is unable to breathe. The "whoop" is caused by the noisy indrawing of breath when the fit stops. The face may become blue and congested. Bronchitis is usually present, and bronchopneumonia may result as a complication, so inoculation of all children before the disease has a chance to strike them is most important.

Once whooping cough has begun, there is no specific treatment, although modern drugs can reduce the frequency of the fits of coughing. The antibiotic chloramphenicol has been used for this disease, but the general opinion is that it is ordinarily of little benefit. Chinese physicians once described whooping cough as the "hundred-days cough," and the cough may, indeed, continue for at least a hundred days.

Food Poisoning Diseases.

Strictly speaking, there is no such thing as "food poisoning" if one is thinking of "poisoning" in terms of anything apart from germs. But not so long ago it used to be thought that decomposition of food in itself produced poisons known as "ptomaines" which were deadly to those who swallowed them. All food poisoning is caused by infection of food with bacteria and by no other cause—unless, of course, we are thinking of the kind of poisoning which is the concern of the lawyer rather than the medical man.

Here we are considering those diseases which are commonly spread by contaminated food or drink. The classification is not scientific, but then no scientific classification has as yet been devised. First, we shall deal with typhoid, paratyphoid, and dysentery—uncommon here in Britain, although Sonné dysentery is fairly frequent. Then there is gastro-enteritis (which means irritation of the stomach and intestines), which is caused by staphylococci and the germs of the salmonella group, and lastly, botulism, which is rare.

Typhoid and Paratyphoid. These diseases are spread by infected water, food, or hands—especially uncooked food, such as milk, salads, oysters, and shellfish. Flies, too, play some part in spreading the disease. Some people are "carriers" and carry and excrete the germs without being themselves affected; for example, "Typhoid Mary," a carrier in the United States in the early years of this century, spent a large part of her life in custody as a public danger, although she did not show any symptoms of typhoid. Nevertheless, this woman caused a great deal of illness in others in her chosen profession of cook.

The influence of Chadwick's propaganda for pure water supplies is shown by the fact that deaths from typhoid, still 332 per 1,000,000 in 1870, fell to 198 per 1,000,000 at the beginning of this century. In the 1920s the death-rate was only 25 per 1,000,000, and now it is even less.

Typhoid fever begins like most fevers with headache, raised temperature, and general feeling of unwellness. This stage lasts about a week, and then the rash appears in the form of rose-red spots on the front of the chest and abdomen and on the back. In the second week there is great weakness, sometimes diarrhœa, flatulence, and mental dullness, together with dry and cracked lips and tongue. The third week is the week, in hopeful cases, of gradual decrease in temperature and other symptoms, and the fourth week is the week of convalescence.

Complications are perforation of the intestine (which needs surgical treatment), delirium, and bronchitis.

Paratyphoid fever is a milder form of typhoid (there are two forms, A and B); ordinarily it can be diagnosed only by scientific tests. The main thing is to inoculate contacts with T.A.B. vaccine and to protect food supplies; treatment is with chloramphenicol.

Dysentery. Dysentery may be caused *either* by a bacterium or an amœba; the first type is known as bacillary dysentery, the latter as amœbic dysentery (which is dealt with under tropical diseases). Infection is spread in much the same way as in typhoid. There is high fever, abdominal pain, and diarrhœa, at first consisting of fæcal matter, then blood and mucus. In severe cases the death-rate used to be over 20 per cent.

Various bacilli cause dysentery. The common tropical types are the Shiga and Flexner groups, but in this country most epidemics are due to the milder Sonné group.

However, in all these infections sulphaguanidine, one of the sulpha drugs, brings rapid relief, but care must be taken to avoid infection of other people.

Diarrhœa and Vomiting. Leaving out typhoid and paratyphoid fevers and dysentery, there is a group of infections known as "D. & V."—diarrhœa and vomiting. In Britain D. & V. is mostly due to:

(1) Salmonella infection.
(2) Staphylococcal infections.
(3) Other bacteria, ordinarily harmless, such as bacillus coli, when present in sufficient quantity.

Salmonella Infections are the most serious of this group; they affect the small intestine and produce vomiting, severe abdominal pain, and diarrhœa. These symptoms occur about one day after eating infected food and usually clear up within about two weeks, but occasionally death results. Salmonella bacteria are most likely to be found in meat, egg powder, vegetables, and ducks' eggs, but staphylococci are liable to grow in milk products, such as ice-cream and cream buns. Food poisoning from staphylococci is seldom severe, and recovery takes place in about a week. Nevertheless, it is extremely infectious, and causes a great deal of lost time in industry and temporary illness in institutions; for it is in such situations that it is most likely to occur.

Staphylococcal Food Poisoning has greatly increased in recent years, so it is important to know what circumstances are likely to cause it. The reason for its increase has nothing to do, as many people suppose, with the greater use of canned foods, but it has much to do with the greater use of communal feeding and canteen meals. It is *possible* for bacterial toxins in infected food to bring about illness even when the canning process has killed the bacteria, but it is certainly extremely rare. Canned foods, in fact, are much safer than so-called "fresh" foods in this respect—except when they have been opened, left about, and then re-heated. The same applies to the re-heating of any kind of food.

The real enemy is the canteen worker with a boil, a discharging nose, dirty hands, or a septic finger. Occasionally food may be infected in the larder by rats or mice, but the sort of canteen or restaurant where this can happen has little to commend it! Frankly, these infections are caused by dirty or stupid people who do not realise that their sore finger or boil can become someone else's diarrhœa and vomiting. Where children are concerned, the outlook is potentially more serious, and in the early part of this century the Summer-time "procession of baby coffins" was all too familiar. Infection is much more common in artificially fed babies or in older children who eat infected ice-cream. However trivial the condition may seem, diarrhœa and vomiting with fever in a child should never be ignored. Those in charge of canteens or restaurants must ensure that staff is supervised, that anyone with a septic infection is put off duty, and that all know about washing after visiting the lavatory and absolute cleanliness.

Bacilli normally present in the intestine, such

as bacillus coli, can cause infections if absorbed in large amounts, or if of a different strain from those in the patient's intestine. They are not usually serious.

Botulism. Now uncommon, this is the disease which used to be known as "ptomaine poisoning" on the theory that it was caused by poisons produced by bad food apart from germs. In the 1920s a party of picnickers at Loch Maree in the Scottish Highlands developed botulism and a number died, with the result that the disease attracted much public attention. Botulism is caused by a germ, the bacillus botulinus, which is peculiar in that, like tetanus, its poison attacks the nervous system rather than the intestines, resulting in fits, double vision, paralysis beginning in the face and spreading downwards, and difficulty in swallowing. It is found in tinned fruits or vegetables containing the toxin even when the germ has been killed, but, as we have already seen, the toxin comes from the bacilli, not from decomposition of food as such (in fact, food does not decompose in the absence of germs). Death is common in botulism, but an antitoxin is now available which, if used in time, can cure the disease.

Tuberculosis. No disease causes more public concern, and no disease is more difficult to describe, than tuberculosis; for, like the streptococcus or the staphylococcus, the tubercle germ can attack many different parts of the body and manifest itself in many ways. Furthermore, it is a widely spread disease, infecting not only humans but also cattle, birds, and reptiles. But here we shall be concerned with those types common to Man—the human and bovine (*i.e.*, the type occurring in cattle which can be spread to man by infected milk).

The tubercle bacillus is particularly hardy, so that when coughed or spat out on the ground it continues to be infectious for a long time. Infection is therefore caused by: (*a*) drinking infected milk; (*b*) droplet infection through having germs coughed in the face; (*c*) breathing in infected dust. In other words, tuberculosis is caused by absorption through either the lungs or the intestines; the former is common in adults, the latter in children.

But there is a good deal more to the problem than this; we know, for example, that over 90 per cent. of people in industrialised countries have been infected with T.B. in early life and have conquered the infection. So the question arises: what conditions predispose to T.B.—why do some people get over the early infection and others not? There are two answers to this question: one is certain—that those who are impoverished and do not get enough food are liable to T.B.; the second is not so certain—that mental stress plays some part. Yet there is reasonably good evidence that such stress as a broken love-affair can cause lowered resistance to breakdown so that when germs are encountered infection will occur.

In children, lung tuberculosis is not common, but tuberculosis of the bones and glands is, as is also infection in the abdomen, the kidney or spine, and, worst of all, tuberculous meningitis. These are often of the bovine type from infected milk. Ordinarily, T.B. in children is less serious than adult infections; but tuberculous meningitis used to be almost invariably fatal until streptomycin was discovered.

Adult tuberculosis usually occurs in the lungs or the pleura—the thin membrane surrounding the lungs. In younger people miliary tuberculosis, which is a form of T.B. blood-poisoning or septicæmia, is a very serious condition, and the infection spreads throughout the whole body in a few weeks.

Lung infection begins gradually in someone who has previously felt unwell. There may be cough, and later blood-stained sputum (although blood which is coughed up does not necessarily prove that T.B. is present). Whatever means of treatment are used, the struggle between disease and patient is likely to be fairly long, but the outlook is now good. The closure of the Swiss sanatoria is due partly to modern disbelief that air in one place is better than that in another, but mainly to improved treatment.

Prevention depends on legal action ensuring tuberculosis-free herds of cattle; on control of spread of the disease by those "open" cases who carry germs in their sputum; on the use of vaccination in childhood with B.C.G. vaccine (which you can ask your doctor about).

Many methods are used in treatment: new drugs, such as streptomycin, isoniazid, and P.A.S., lung surgery, rest, and so on. At any rate, tuberculosis is being got under control, but anyone who is worried can get a free X-ray at the nearest Mass Radiography Centre. For children, there are skin tests to show whether there is suceptibility to T.B.

Septicaemia. Commonly known as "blood-poisoning," is one of those diseases of which textbooks prior to the Second World war used to say: "death usually occurs."

Blood-poisoning occurs generally by spread from some septic area such as a wound (or even a small prick), after childbirth, or any place where certain germs have got admission to the body. The most usual germ is the streptococcus, although the pneumococcus—which ordinarily causes pneumonia—and the staphylococcus may also cause septicæmia.

Fever comes on suddenly and rises rapidly with headaches, sweating, and shivering. The patient is obviously very ill, and later there is wasting and delirium. The white blood cells increase in number. Septicæmia sometimes occurs without any apparent local infection in those who are weak and debilitated.

Pyaemia is a type of septicæmia which leads to the formation of numerous abscesses throughout the body. Its symptoms are the same as described above, except that the causative germ is usually the staphylococcus, and abscesses are found which may need surgical treatment.

However, in both conditions the state of affairs has been revolutionised by the use of the sulpha drugs and antibiotics; cure is now the rule rather than the exception.

Septicæmia should be suspected when any small wound or cut is followed by high temperature and the symptoms described above.

The word "*Toxaemia*" is used when the germs stay in their original position and produce symptoms by spreading their toxins throughout the body. Tetanus, diphtheria, and some kinds of childbirth infection come into this category; the symptoms may vary from mild disturbance to severe illness.

Meningitis means inflammation of the meninges, the covering which, like a layer of plastic, lies over the brain and spinal cord, just as the pleura covers the lungs and the peritoneum covers internal organs in the abdomen. (Hence inflammation of the pleura is known as pleurisy, and inflammation of the peritoneum as peritonitis.)

Various germs may cause meningitis, for example, the bacillus of tuberculosis, the pneumococcus, which ordinarily causes pneumonia, and the streptococcus or staphylococcus, but ordinarily the word refers to *Cerebrospinal Meningitis* or "spotted fever" caused by the meningococcus and occurring at times as an epidemic. It is commonest in the years from infancy to the early twenties, and begins suddenly with headache, vomiting, and fever. The temperature rises quickly, and pain develops in the back and legs; on the second or third day a rash appears on the body, and particularly on the inside of the thighs. Later there is stiffness of the neck, the head may be drawn back, vomiting persists, and the headache can be so severe as to cause the patient to scream with pain.

Fortunately, this type of meningitis (and most of the others) respond to treatment with antibiotics or the sulpha drugs, so the risks are very much less than formerly.

Pneumococcal Meningitis is an unusual complication of pneumonia, and the septic types (*streptococcal or staphylococcal*) arise either following an infected fracture of the skull or from infection of the ear or mastoid.

Tuberculous Meningitis has already been mentioned; originally always fatal, it is now treatable with streptomycin.

All these diseases are very much a matter for

specialist and hospital treatment, but it is worth while mentioning *benign lymphocytic meningitis*, in which, although all the smyptoms of meningitis are present, recovery without specific treatment is invariable. Meningitis, which was during the First World War and after what polio is to us now, is no longer common, and when taken in time is easily treated.

Tetanus is usually known as " lockjaw " because there may be difficulty in opening the mouth, although this is simply part of a spasm of all the muscles of the body. The tetanus bacillus is found in rich soil—hence the disease is less common in desert areas—and tetanus resembles rabies in that: (*a*) it enters at a wound; (*b*) it affects the nervous system; (*c*) it results in fits and ultimately death.

However, active immunisation with T.T. (tetanus toxoid) has resulted in the disease becoming uncommon, and even when developed, treatment with antitoxin, anæsthetics, and curare may lead to cure.

The bacillus is anærobic (*i.e.*, does not use oxygen) and is most likely to occur in such situations as when a man digging manure or working in his garden sticks a fork through his foot, or, in war-time, when he is wounded in soil contaminated with manure.

Undulant fever, also known as Malta fever or abortus fever, falls into two types: melitensis, which infects goats, and abortus, cattle and pigs. Man gets the disease by reason of close contact with or drinking the milk of infected animals. (The name abortus is given because abortion is produced in cattle and sows.)

In Undulant Fever, as one would suppose, the fever goes up and down for two to three weeks; it may then go down and rise again, persisting for many months. The disease may occur in Britain, but modern drugs are on the whole successful in dealing with it. A striking feature of the disease is the combination of a high termperature with an appearance of relative well-being.

Another disease carried by mammals is *Glanders* or *Farcy*, spread by horses. In glanders there is discharge from the nose and sometimes pneumonia. Occasionally the disease is fatal. In farcy abscesses form, usually along the lymph vessels. Both conditions are very contagious, and treatment is a matter for a specialist; infected horses should be destroyed.

Cholera. Cholera could be classified under the head of food-poisoning, because it is mainly spread by infected water (however, like typhoid, it can also be spread by flies, infected food, and carriers); it could also be classified as a tropical disease, since, although it used to be found in Europe, it is now mainly rife in India.

Also like typhoid, cholera is caused by a bacillus, and can be prevented by early inoculation and care over food supplies—boiling water and milk, washing uncooked foods in chlorinated water, and keeping flies away.

The fever begins in the usual way with a short incubation period, followed by abdominal pain, severe vomiting, and diarrhœa. Later with the loss of fluid from the body there may be cramps in the muscles, diarrhœa increases, and the motions become of the typical " rice-water " type —*i.e.*, there is no solid matter, and the appearance is that of water to which a little milk has been added. This stage is followed by collapse, with low pulse and cold hands and feet. Death, if adequate treatment is not available, results in about 70 per cent. of cases.

Anthrax. The bacillus of anthrax, like that of tuberculosis, can exist outside the body for long periods, and, like that of tetanus, then takes the form of spores or seed-like bodies. It is spread by infected cattle and horses, which get the disease from eating grass containing spores.

In human beings the form the disease takes depends on where the germ alights; sometimes it comes from infected shaving-brushes, when it causes a large sore, like a boil, on the face, known as " malignant pustule "; sometimes it develops in those who inhale the dust from infected hides or wool (hence the name " wool-sorters' disease," which is a form of bronchitis with blood-stained sputum); lastly it may arise through eating infected meat, when the result is intestinal anthrax.

In all cases the outlook is serious. Death is common, preceded by a high temperature, skin symptoms in the first instance, lung symptoms in the second, and food-poisoning symptoms in the third. Serum and arsenical preparations were formerly used, but now the suplha drugs seem to offer more promise.

Diseases Caused by Fungi.

There are only two important groups of disease caused by fungus: the serious *actinomycosis* and the relatively harmless, if unpleasant, *ringworm*. Ringworm or tinea will be dealt with later; it affects the hair, the body, the groin (dhobie itch, already referred to), and the feet (athlete's foot). Actinomycosis is spread by a fungus in barley and grasses which may reach the human mouth, settle around bad teeth, and thence pass to the lungs, the bone of the jaw, and even to the intestines or brain. Fortunately, this unpleasant fungus, which was once difficult to eradicate, has proved susceptible to penicillin.

The Venereal Diseases.

The venereal diseases are those caused—or at least that is what the name means—by the goddess of love, Venus. Venus, of course, causes a great deal of trouble, but venereal disease is not necessarily the worst she can do. Venereal disease is spread by sexual intercourse with an infected person.

Gonorrhoea is the result of an infection by the gonococcus (*Neisseria gonorrhoea*) and ordinarily comes on after an incubation period of three to seven days. However, babies can get an infection of the eyes, known as ophthalmia, from their mother if she is infected, and gonorrhoea in young children is often the result of being in contact with infected towels or clothes. The disease in adults is evident when there is a thick, creamy discharge from the sexual organs and sometimes pain on passing water; in infants ophthalmia is prevented by the use of silver nitrate eye-drops at birth. Gonorrhoea is fairly easily cured by the use of sulpha drugs or penicillin; but unfortunately venereal disease is increasing in recent years and drug-resistant forms are becoming more common.

Syphilis is a serious venereal disease caused by a spirochete (*Treponema pallidum*). Stories about lavatory seats are simply stories, although it is occasionally possible to get syphilis by other than sexual means: for example, it has happened that a man playing football has been infected through his hand being grazed by the teeth of someone with syphilis. But this is very unusual, although kissing can spread the disease. Children, too, can be born with syphilis (the so-called congenital syphilis).

Adult syphilis begins with a sore, known as a hard chancre, at the point where the sporochæte of syphilis has entered; this may be on the lips, through kissing; on the sexual organs, through intercourse; and very rarely, as explained above, elsewhere. In a short time the chancre disappears and all may seem to be well, but this primary stage is followed by a secondary stage with sore throat, a rash, headache, and enlargement of glands. This, if left alone, also clears up, but is followed by the tertiary stage, in which a chronic infection develops in some part of the body which, presumably, is most susceptible in the particular individual. Thus there may be chronic syphilis of the skin, the bones, the heart, liver, or nervous system.

In the nervous system, the commonest forms are the two diseases of *tabes dorsalis*, in which the spinal cord is infected, and G.P.I. (general paralysis of the insane), in which the brain and mind are affected. These will be discussed under Nervous Diseases.

In congenital syphilis the pregnant mother gives her child syphilis. Such infants are often stillborn or premature, they look wizened, like a little old man, and amongst other symptoms are eye

disease, "snuffles," a flattened nose, and when the adult teeth appear the front ones may be notched at the biting surface.

The treatment, of course, is very much a matter for a specialist, but diagnosis is usually made through the Wassermann blood test. It was for syphilis that Ehrlich produced his "magic bullet"—an arsenical drug, known as salvarsan, which could attack the organism selectively without harming the body and was the first of the modern specific drugs. Present-day treatment is with penicillin. G.P.I., once hopeless, is now dealt with by malarial therapy with a good deal of success. Penicillin alone is often adequate.

It is important to understand about venereal disease in general: (1) that it happens to many people who are no worse than anyone else; (2) that many patients believe themselves to have V.D. when, in fact, they have not; (3) that the best thing to do is to see your doctor as soon as possible—he is not concerned with your morals, and the sooner you go, the sooner you will get well; (4) every sore in the sexual area need not be V.D. There are other diseases which may be contracted as venereal infections.

Chancroid produces small septic ulcers around the sex organs, with swelling of the local glands in the groin, which may suppurate. It is caused by a bacillus, and can usually be cleared up by sulpha drugs within a week. Scabies and lice often pass from one body to another during sexual intercourse, but are not usually thought of as venereal in origin, although in many cases they are.

Tropical Diseases.

Nothing is more difficult than to define the term "tropical diseases." One might define them as the diseases which occur in tropical climates—but then measles occurs there too; and if they are defined as those diseases which are found *only* in the tropics, the solution is no easier, since leprosy, cholera, smallpox, and typhus are usually listed as tropical diseases, yet were found in this country until fairly recently—and the odd case still is.

But what a story could be told about the conquest of those infections which were—and many still are—the scourge of humanity! One day when generals and dictators are forgotten we shall remember that great international army of physicians and bacteriologists who have saved millions of lives and infinitely reduced human suffering: Koch and Ehrlich of Germany, Pasteur and Roux of France, Ross and Jenner of Britain, Reed of America, Noguchi of Japan, and many others. We shall remember how the Jesuit priests brought quinine from Peru to Europe in 1638, the first drug to save people from malaria; how in tropical heat Ronald Ross (1857–1932) peered for hours through his microscope to discover the connection between malaria and the mosquito until the sweat running from his brow rusted the instrument; how Major Walter Reed's work in Havana (1851–1902) made possible the building of the Panama Canal, and think, too, of the American soldiers who died in helping him to find the cause of yellow fever. In mentioning Jenner once more, we should recall Lady Mary Montagu (1689–1762), who brought the practice of vaccination to England from Turkey—or, rather, the practice of "variolation," which meant inoculating with the pus from smallpox cases. This was, of course, a dangerous practice, but the idea was there. Noguchi, one of the great bacteriologists of the nineteenth century, was the son of a poor peasant. He often had to steal to get enough bread even to keep alive, but was later to help in our understanding of syphilis and many tropical diseases.

Yet there is still much to do. Take, for example, the case of Egypt, one of the world's poorest countries, supporting with the help of water from the Nile about 24 million people. But if the river gives food and drink it does other things; for it carries the disease of bilharzia, which kills thousands of peasants yearly. In the villages of Egypt as many as 90–100 per cent. of the population suffer from this terrible disease. The infantile mortality rate is the second highest in the world—29·5 per cent.—seven times higher than that of Holland; the average expectation of life amongst the lower classes is thirty-one years, of the upper classes fifty to sixty years. The country is ridden with bilharzia, ankylostomiasis, malaria, plague, amœbic dysentry, typhus, tuberculosis, and pellagra. Blindness, due to trachoma and other diseases, affects tens of thousands. Such a situation cannot be treated simply by pouring drugs into the country; what is necessary is social control, to enforce purification of the water supplies, the use of insecticides such as D.D.T. to kill the disease-bearing pests, and removal of the causes of extreme poverty (tuberculosis and vitamin deficiencies which are common in Egypt are diseases of malnutrition).

Relapsing Fever, common in India and Africa, is caused by bad hygiene (rubbing infected lice into the skin); the germ is a spirochæte, similar to that of syphilis, but the disease is non-venereal. Relapsing fever gets its name from the fact that the temperature remains high (103–106°) for about a week, returns to normal for a week, and rises again. There may be three to five relapses of this sort. Cure can be brought about by the arseno-benzol drugs used in syphilis. Lice, of course, should be dealt with.

Epidemic Jaundice (also known as Weil's disease or—if you prefer it—ictero-hæmorrhagica spirochætosis), is also caused by a spirochæte, and spread by rats. Now it is rarely found in Europe, although it occurred in the trenches during the First World War, in men working in sewers, and in the women who worked in the fish market of Aberdeen, which at one time was rat-infested. It is rarely fatal, but leads to high fever and jaundice. Anti-syphilitic drugs are useless, but some of the new antibiotics may help.

Yaws is also a spirochætal disease, common in the tropics and particularly in children. It is unpleasant, but not serious, and tends to clear up in a year or so. There are raspberry-like growths on the skin, which disappear with the drugs used in syphilis (although the condition is non-venereal). The Wassermann reaction, positive in syphilis, is also positive in yaws.

Leprosy. Whereas syphilis, relapsing fever, epidemic jaundice, and yaws are caused by spirochætes, leprosy is caused by a bacillus resembling the bacillus of tuberculosis. Leprosy, in fact, should not be included here at all, for it is non-spirochætal, and not necessarily a tropical infection. Apart from the difficulty of classification, many popular beliefs about the disease are untrue. It is *not* the oldest disease afflicting man; *not* a disease confined to tropical countries; it is *not* very catching; *not* hereditary, *not* incurable; in leprosy the fingers and toes do *not* drop off; it is *not* a divine punishment for wrongdoing. So there are many misunderstandings about this disease, and placing it in the wrong part of the medical section is probably the least.

Leprosy is a serious disease not because of disfiguring light-coloured skin patches and lumps, but because it destroys peripheral nerves. Leprosy may disappear spontaneously, or it may progress until the face is lion-like and the hands and feet wasted and ulcerated. The disease rarely kills, but it is the world's greatest crippler.

Leprosy was once fairly common in colder Western countries, though its extent was exaggerated. The great majority of the 15 million people who suffer from leprosy live in tropical countries, but it still exists in Iceland, Japan, Korea and some of the southern states of the United States. Prolonged and intimate contact with an "open" case is said to be the main mode of infection, but only one infected husband in twenty passes leprosy to his wife.

The sulphone drugs have revolutionised the treatment of leprosy. Given early diagnosis and adequate treatment, the great majority of sufferers could be cured. Established deformity (such as claw hand, drop foot, paralysed eyelids) can be mitigated by reconstructive surgery, although lost sensation cannot be restored.

In the past, only Christian missions were concerned with the plight of the leprosy sufferer. Now, non-sectarian voluntary agencies, Governments and the World Health Organisation have joined in the fight against the disease. Enough is known to control the disease, but not enough is

being done, as only one victim in five is at present getting treatment.

Plague is another disease caused by bacteria, common in Europe at one time, but now largely restricted to Asia. Nevertheless, it caused millions of deaths in Europe during the years 1348–49 and 1665 and was the "Black Death," which, indeed, changed the course of history. Interested readers may read Hans Zinnser's *Rats, Lice, and History* about this aspect of the disease. Plague is carried by the bite of the rat flea, but, once people become infected, spread may occur from one to the other by droplet infection—*i.e.*, by coughing and sneezing. After an incubation period of two to ten days, fever develops, rather like severe influenza, and in a day or two the glands in the groin begin to swell, followed perhaps by swelling of the glands elsewhere. This is the usual type of plague, but it is also possible to get disease of the lungs from droplet infection and blood-poisoning from infection of the blood-stream. Both the latter types are almost invariably fatal, and even the glandular type (bubonic plague) has a mortality of about 80 per cent. The vaccine has given place to streptomycin and sulpha drugs which are also used on contacts.

Although we have little space to discuss the subject of plagues and epidemics in general, it is worth noting that serious epidemics have almost always followed wars, revolutions, and economic and political collapse. Thus the Black Death followed the break-up of the Roman Empire, and, in the fourteenth century, accompanied the end of mediæval civilisation. The Napoleonic wars were followed by other epidemics, and the wars of the 1830s in Europe were followed by influenza. In the most widespread outburst of influenza after the First World War, more people were killed by the disease than in all the fighting of four years. It is a reflection on the peculiar mentality of Man that this devastating epidemic, which affected almost the whole world, occupies little space in his history books—we still, with few exceptions, regard history as the doings of kings, queens, and generals. Yet, in 1918, 20 million men, and women, and children died from influenza, and no cure has, as yet, been found! Later we shall see that many millions of people die yearly from starvation or vitamin deficiencies But these facts—the real facts of life—we rarely hear about.

Protozoal Diseases.

Nearly all the diseases caused by protozoa are tropical diseases, although one of the best-known protozoans is the harmless amœba found in British ponds. Protozoal diseases are caused by these organisms, large in comparison with bacteria which are really one-celled plants. Viruses are neither animals nor plants, are much smaller than the other two groups, and have some distinctive characteristics described elsewhere.

The only important diseases caused by protozoa are sleeping sickness or tryanosomiasis, malaria, and amœbic dysentery (as contrasted with bacillary dysentery), another disease, leishmaniasis—also known by the numerous names of kala-azar, dum-dum fever, and, in milder form, Delhi boil, Oriental sore, or Bagdad sore—will also be mentioned briefly. These infections are few, but important in their influence on Man; for, as Dr. Clark-Kennedy has pointed out, malaria until recently was responsible for one-fifth of all human sickness, sleeping sickness not so long ago caused a large part of Central Africa to be uninhabitable, and in some areas of the tropics there are probably more people with, than without, amœbic dysentery.

Malaria. The word, of course, means "bad air," just as "influenza" means "influence"—in Italian *influenza di freddo*—the influence of cold. Human beings have a natural tendency to suppose that, when two events occur together, then one must be caused by the other. Yet, although malaria and "bad air" may often go together, and influenza and cold, it does not follow that bad air (whatever that may be) causes malaria nor that cold causes influenza. In fact, the anopheles mosquito carries the amœba of malaria, and the mosquito prefers climates which some people might describe as "bad," but it is the amœba, not the air, which causes the disease. Anyhow, the unfortunate mosquito might well use the phrase honoured by many generations of schoolmasters: "It hurts me more than it hurts you!" For the mosquito, too, is sick, and passes on its sickness to the person it bites.

There are several types of plasmodium—which is the scientific name for this amœba—producing attacks of fever varying in severity and frequency: benign tertian, quartan, and malignant quartan. Entering the body from the mosquito bite, the parasites penetrate the blood cells, multiply there, and finally burst into the blood stream. When this happens the temperature rises, and then they return to the cells to carry out once more the same procedure. Depending on the type, the attacks of fever may be at intervals of three or four days, severe or milder. When someone with malaria is bitten by a mosquito the infection can be transmitted to the next person it meets, but malaria is not infectious from one person to another directly. Quinine, of course, is the time-honoured remedy, but many other drugs are now available: mepacrine, palmaquine, atebrin, and even a sulphonamide derivative known as promin have been tried. The drug must be taken long enough for the infection to die out, otherwise relapses can occur even after leaving a malarial country (but it is only fair to say that, just as some people continue to give themselves the title of "Major" when they have left the Army, so others long in Britain continue to describe attacks of cold or 'flu as "my old malaria again," when, to say the least of it, they are exaggerating).

Important as are the drugs used in the treatment of malaria, even more so is the control of the parasite-bearing mosquito. The eggs of mosquitoes hatch in water, and there the young or larval forms can be attacked by pouring oil on the surface of pools so that they are unable to breathe, or by introducing small fish which have a partiality for them. Adult mosquitoes can be killed by D.D.T. and other insecticides or kept away by nets over beds and skin creams. Finally, anti-malarial drugs can be taken in dangerous areas. Whereas anopheline mosquitoes were once well on the way to getting rid of Man, now Man is well on the way to getting rid of mosquitoes.

Blackwater Fever is a sequel to malaria in tropical Africa and some parts of India. Rather illogically, it is described as "Blackwater," although the urine is red and the skin is yellow but the result is due to breaking down of the red blood cells by some malarial toxin. Possibly too much quinine may help in producing the illness. Treatment is to give plenty of fluids and no quinine or any other anti-malarial drugs in the early stages. The death-rate is about 25 per cent.

Trypanosomiasis or sleeping sickness—not to be confused with *sleepy* sickness, which has already been dealt with under the name of encephalitis lethargica—is essentially an African disease (although also found in tropical America) spread by the tsetse fly. Its cause is the type of protozoan known as a trypanosome, almond-shaped with vibrating membranes at the sides which enable it to move through the blood-stream, rather like a flat fish in the water.

There are three stages of the disease: first, the stage of fever with enlarged glands and a rapid pulse, which may continue off and on for three years; secondly, the stage of trembling hands, legs, and tongue, vacant expression, and slow and stumbling speech; thirdly, and lastly, the stage of low temperature, apathy, wasting of the muscles, and possibly death.

Treatment is with arsenical drugs—such as tryparsamide or Bayer 205—which give good results in early cases. Preventive measures in infected areas include the destruction of tsetse flies by insecticide, the cutting down of forests near rivers which are inhabited by tsetse flies, and some authorities have suggested the shooting of big game which may form a "reservoir" of the parasites, whence tsetse flies can carry them to human beings. For similar reasons infected

people should not be allowed to move to non-infected areas.

Amœbic Dysentery, also known as *Amœbiasis*, is caused by the *Entamœba histolytica*, an amœba whose cysts are found in food, water, or spread by infected fingers or flies. There is mild fever and diarrhœa which contains blood. The disease may become chronic, and can cause abscesses, usually in the liver but sometimes in the lungs. Amœbiasis is treated and usually cured by injections of emetine hydrochloride, but in the chronic phase the drug known as Yatren is used in the form of an enema.

Leishmaniasis, kala-azar, or dum-dum fever, is another amœbic disease, probably spread in this instance by the bite of sandflies. It is also known as tropical splenomegaly—enlargement of the spleen in ordinary language—since infection results in enlargement of the spleen and liver, low, irregular fever, and death within a year or so. A milder form, affecting the skin, is known as Delhi boil, Oriental sore, or Bagdad sore, does not lead to kala-azar, and is fairly readily cured. The cure for both conditions is to give injections of tartar emetic, which reduces the death-rate from kala-azar from 80 per cent. to about 5 per cent.

Diseases Caused by Parasitic Worms.

Many types of worms infest human beings and other animals. They are interesting for such reasons as their size (which may range from the almost invisible to 30 ft. or more), their life histories, and their serious or trivial consequences on their hosts. We shall mention only a few groups here, and mainly the ones likely to be met with in Europe—the tapeworms, the roundworms, and the threadworms—although some tropical types will be described briefly.

Tapeworms, as we have seen earlier, like many other types of intestinal worm, lead a double life. What usually happens is that the worm breeds in the human intestine, the eggs pass out in the fæces, and are then swallowed by animals eating contaminated material. In the animal the eggs hatch out into larvæ—primitive forms which penetrate the muscle, forming cysts—and Man is infected in turn by eating its meat. Thus *taenia solium* gets into the flesh of pigs, which, if imperfectly cooked (measly pork), causes infestation of the intestine in Man. It reaches a length of about 10 ft. *taenia saginata*, which reaches a length of about 20 ft., is spread in imperfectly cooked beef, and in Baltic countries *dibothriocephalus latus* gets into the human intestine from caviare or undercooked fish. It reaches the awesome length of 30 ft.

Now all the worms we have mentioned so far are found in the human intestine, and the cysts, which are much more dangerous and unpleasant, in the animal's muscles. But in some worms the reverse happens, with the adult in the animal's intestines and the cysts in Man. Thus in Australia the dog tapeworm (*taenia echinococcus*) produces cysts in both sheep and Man. This is known as hydatid disease, and may remain unsuspected until cysts in the lungs, liver, or elsewhere become infected or rupture. *Trichinella spiralis* is similar in action, being found in the intestines of pigs and getting into the muscles or other organs of Man. The main difference is that this worm migrates from the pig's intestines into its muscles, whence it reaches Man in undercooked pork meat or sausages. The muscular cysts cause swellings and sometimes pain. There are changes in the blood, swelling of the face and leg in the early stages, and fever. A minor epidemic occurred in England in 1941. *Taenia echinococcus* and *trichinella spiralis* are small—not more than ¼ in. in length—but are more serious in their consequences than the large worms. Treatment is very difficult, and ordinarily all that can be done is to deal with individual cysts when they make themselves apparent.

The large tapeworms, *taenia solium* and *saginata* and *dibothriocephalus latus*, produce varying symptoms or none at all. Usually they are not discovered until some segments of the worm are excreted, but there may be mild indigestion, excessive hunger, and occasionally anæmia. However, when the worm is discovered the patient, not unnaturally, is likely to become anxious and uncomfortable at the thought of "having" a tapeworm; these symptoms are caused by the worry rather than the worm.

Treatment is, of course, a matter for a doctor, but purging followed by extract of male fern is usually successful. One has to make sure that the head of the worm has been removed, otherwise it will continue to grow.

Roundworms are similar both in appearance and size to ordinary earth-worms and the eggs reach Man, not from an animal, but from the contaminated fingers of someone else who handles food. They give rise to no symptoms, and are noticed only when discharged in the fæces or occasionally vomited up. They can be removed by the use of santonin.

Threadworms, as the name suggests, are like small ½–¼-inch-long pieces of white thread. They are very common in children, and live mainly in the cæcum—*i.e.*, the part of the large intestine near the appendix. The males, which are the smaller ones, remain there, but the females pass down towards the rectum at night-time and lay their eggs in the area around the anus. Infection is by contaminated hands handling food—especially uncooked food—and water. Threadworms are not serious, and cause few symptoms other than itching around the anus and between the legs, but heavily infected children may show symptoms of anæmia. The nervousness often shown by such children is usually the result of the irritation produced by the worms in the anal region. Infection is not common in adults, and in children tends to disappear at puberty.

Treatment is, in theory, simple; for the worms are easily destroyed by a number of drugs, such as gentian violet, thymol, or one of the proprietary remedies. Ointment is applied to the itching area, and the child should be prevented from scratching. However, since the eggs may lie about the house for some time, reinfection often happens, especially if there are several small children in the home who may pass the disease from one to another.

The idea that intestinal worms in general are likely to cause loss of weight by absorbing food eaten by the patient is largely mistaken: for, although it is true that they do live on this food, the amount taken is certainly not enough to be significant.

Tropical Worms. Bilharzia has been mentioned before in connection with its frequency in Egypt, although it is also found in other parts of Africa, Arabia, and Iraq. There are two main types: one infecting the bladder (*schistosomum haematobium*), the other the rectum (*schistosomum mansoni*). Bilharzia is more correctly known as schistosomiasis.

The parasite's fantastic life-history begins when a man bathes in infected water, and the small swimming forms known as cercariæ pierce and enter his skin—or they may enter the body by drinking infected water. From the skin they pass to the portal vein below the liver, remain there six weeks until they become adult and then swim against the blood-stream down to the pelvis, where the female lays eggs which have a sharp spine. The eggs penetrate into the bladder or rectum—depending on the type of fluke—and pass out in the fæces or urine. If they enter water they hatch out into small moving forms which seek out a water-snail, develop further in its body, and leave it in the form of cercariæ ready to find a new human victim. The female fluke is slender and round, about 1 in. in length, the male, flat and leaf-shaped, is about ¾ in. long, and, as we have seen, their grisly courting takes place in the portal vein, whence the impregnated female

passes to the bladder (hæmatobium) or rectum (mansoni) to lay her eggs.

Infection results in raised temperature and, in the urinary type, blood in the urine; in the intestinal type blood is found in the fæces, and there are symptoms resembling dysentery—*e.g.*, diarrhœa. Treatment in both cases is by injections of antimony tartrate. Needless to say, attempts should be made at prevention by telling people to avoid infected canals (usually easier said than done), and by periodically cutting off the water supply to the canals to kill the snails.

Hookworm Disease, or ankylostomiasis, is found in many parts of the world, especially in miners who work on damp ground. The tiny worm enters the body usually through the feet, passes through the blood-stream to the lungs, eats through into one of the bronchial tubes, climbs the windpipe, and passes down the œsophagus into the stomach to end up in the duodenum. It causes anæmia, can be fairly readily cured, but is occasionally fatal.

Elephantiasis. Some types of parasitic worm are spread by insects. Thus in *Filiarisis* mosquitoes inject by their bites the infantile forms of a tiny worm which enters the lymphatic channels; there the blockade they cause leads to the swelling of the legs and the lower part of the body, known as elephantiasis.

PHYSICAL INJURIES

INTRODUCTION.

In this section we shall inevitably discuss much that could be described as Principles of First Aid. You cannot learn First Aid from a book, even if you read one of the excellent first aid manuals, like those published by the St. John Ambulance Association. The only way is to join one of their many classes of practical and theoretical instruction which are held in all parts of this country and many others. There is much to be said for many more people receiving instruction, to judge by the level of general ignorance and ineffectiveness to be witnessed at most road accidents before the ambulance comes.

The most difficult thing to learn is what *not* to do. When a patient is knocked down in the road, people instinctively seem to want to drag him immediately to his feet, or otherwise pull him on to the pavement away from the traffic. Someone will have entered the nearest shop and be emerging with a chair so that the casualty can sit down. Before long a hot strong sweet cup of tea has arrived, and this or some other beverage is being poured into him. All this is instinctive, and all of it is wrong. Do *not* move the patient until you are sure he has no fracture which will be further aggravated by movement. To take an extreme case, a fractured spine clumsily moved may result in permanent widespread paralysis. Guard your patient from the traffic but only move him when you are certain it is safe to do so. If he has any injury which is likely to require a general anaesthetic on arrival in hospital (and this applies to most fractures) do not give anything at all by mouth. No anaesthetic can be given to a patient who has eaten or drunk anything in the previous three hours, in case he vomits while unconscious and dies of obstruction of his airway. Keep your patient warm (do *not* warm him up artificially) keep his head low, and unless he is bleeding severely or has stopped breathing, do nothing but protect him from the ministrations of the uninstructed until the ambulance comes.

Injuries to the Head and Back.

The head contains the brain, an organ with a number of inconvenient properties from the point of view of injury. Its very great importance is matched by its very great vulnerability as a tissue. Its consistency is that of stiff junket. It is quite incapable of repair once damaged and cannot heal by growing new parts in the way that skin and bone can. So it has to be totally enclosed by protective bone which means it cannot swell without compressing itself dangerously within its box—and this not infrequently happens after injury. Furthermore, any bleeding into the interior of the skull can only occur at the expense of compressing the brain, since the brain box is already fully occupied by the brain. There is a story in first aid known as "Concussion and Compression." It begins with a knock-out blow to the head and this is known as concussion. The patient struck a hard enough blow to the head will lose consciousness, if only for a short time, due to the brain being shaken up. Even slight knocks would do this if the brain were not cushioned by a thin layer of cerebrospinal fluid. Most concussed patients quickly regain consciousness, and for the great majority that is the end of the affair except for a sore head and a headache for a few days. Unfortunately for a minority, even though there may have been no fracture, the blow that knocked them out will also have damaged a small blood vessel on the surface of the brain. These patients may be indistinguishable from the luckier ones at first. They may have regained consciousness and will be just as anxious to go home. They will often be quite lucid for some hours. Surgeons call this the "lucid interval." However, when more than a certain amount of blood has accumulated in the head, and the brain is sufficiently compressed by it the patient loses consciousness slowly, for a second time, and from this phase of "compression" he will not recover unless something is done. The lucid interval can last some hours. Brain surgeons can relieve the compression and save the life of the patient only if they have him in their care when it occurs. This is why *all* cases of head injury who have once lost consciousness (concussion), for however short a period of time, and however lucid they may subsequently appear, *all* must be seen by a doctor and, if thought necessary, observed overnight in hospital, in case they are bleeding and proceeding to compression. There is no way of saving these avoidable fatalities other than by treating all cases of concussion seriously. Fractured skull is potentially even more serious, because the blow will have been harder and, the brain is therefore more seriously at risk.

The spinal cord can be regarded as an extension of the brain which runs down the middle of the spinal bones of the vertebral column. It has the same delicate consistency, and the same inability to recover from injury as the brain. Injury is usually the result of a fracture-dislocation of the spine. The consequences of injury are due to a permanent interruption of its two main functions. All movements of the voluntary muscles are only possible if they are connected by nerves to the brain. Except for muscles in the head, all these "motor" nerves run in the spinal cord. The nerve pathways leave the skull through a large hole in its base and run down in the spinal cord to the required level. They then emerge between the spinal bones and travel in bundles to reach the muscles. Motor nerves for the arm leave the cord between the vertebrae of the neck. Those for the leg leave the cord in the lumbar region in the small of the back. If the nerve supply is damaged in any part of its course, the muscles being supplied become paralysed and are unable to move. It follows that if the spinal cord is damaged, all muscles below the point of damage have been cut off from the brain, and will be paralysed, and this will be permanent because the cord cannot be repaired. Damage to the nerve pathway *after* it has left the cord can often be repaired. Permanent paralysis is only one of the consequences of cord damage, since there is another whole series of nerves running in the cord which carry sensations from all parts of the body to the brain. Therefore there will be loss of sensation as well as paralysis below the point of injury.

It is emphasised that fracture of the spinal bones can occur without damage to the cord taking place. It is when these bones move one over the other, or "dislocate," that permanent cord damage occurs. It is therefore extremely important that cases of back injury be moved

very carefully indeed in order to avoid such a disaster, and special ways of moving such patients are taught in First Aid classes.

Haemorrhage and Shock.

Every part of the body must have a blood supply, or else it will die. It is possible to stop the blood supply to a leg, for example, by fastening a wide rubber bandage tightly around the top of the thigh. This so-called " constrictive bandage " is still mentioned in First Aid books as a desperate means of controlling haemorrhage in a limb. It should hardly ever be used, because by stopping all circulation of blood, the entire limb will die in the course of time. Besides, most haemorrhage can be stemmed by direct pressure on the bleeding point. The tissues of the leg, such as its muscle and skin and bone will begin to die in a little more than half an hour after cutting off the blood supply. The brain, however, will begin to suffer within three *seconds* of its blood supply being cut off, and will die in about three minutes. Thus it can be seen that some parts of the body are more susceptible than others to a failure of the blood supply and the brain suffers earliest of all. Since the brain is where most of the vital functions of the body are controlled, it follows that a shortage of blood to the brain is likely to lead to a " depression of the vital functions "—a state of affairs known to First Aiders as "shock."

Shock occurs in a number of conditions, but is always due to a failure of the supply of blood to the vital functions of the brain for one reason or another. Its usual causes are:

(1) haemorrhage, when there is a general shortage, but the brain feels it most;

(2) severe burns, in which much fluid is lost from the blood as will be seen later; and

(3) certain medical conditions causing acute heart failure in which there is a failure to pump blood to the brain because the pump has failed.

The treatment for shock consists basically of restoring the blood supply to the brain, and where it is caused by loss of blood or other fluid, the treatment is transfusion. Finally, it must be emphasised that treatment is always urgent, since the brain cannot function for long without its blood supply, and once damaged by the shortage, can never be repaired. No attempt is made here to describe such treatment completely, but the most important things are to keep the head low so as to reduce the work the heart must do to drive blood to the brain; and to avoid artificial heating of the body by hot water bottles, etc., which only diverts blood away from the brain where it is needed, into the skin where it is not.

The treatment of severe haemorrhage is to stop the bleeding, usually by firm, direct pressure, and then to remember above all things that even though the bleeding has stopped, there may be a dangerous state of shock from which the patient could die. This can only be prevented by restoring the circulation to the brain, usually by transfusion; so, having stopped the bleeding drive him fast to hospital for the second part of the treatment which may be as necessary to save his life as the first.

There is great confusion over the use of the word " shock." In the lay mind it is a shake-up of the nervous system caused by a fright, or some bad news, or the sight of something nasty in the woodshed. Even in the medical mind it is sometimes confused, and some of the First Aid books confuse it still further. Too frequently they give the treatment as " loosen all tight clothing from neck, chest, and waist; reassure the casualty and ensure a good supply of air." All this, together with grandmother's hot strong sweet tea is perfectly good enough if the patient is only " shaken-up " by a fright or a fall, but it will be dangerously negligent and time-wasting if he is suffering from true shock due to a failure of blood supply to the brain.

Fainting is a special case which can be prevented by keeping the head low in those who feel faint. It is usually self-curing due to the patient automatically falling into a position in which the head is low. If the faint, however, is due to severe blood loss, this is the same as shock in our proper meaning of the word and must be treated accordingly.

Haemorrhage can therefore be a difficult problem. It is even more so when it is internal. This may be in *medical* cases such as in occasional cases of peptic ulceration in which the blood will be vomited and also passed in the stool. Or it may be *surgical*, in the sense of being caused by injury to internal organs. The blood may emerge from one or other of the various orifices of the body, or it may be entirely concealed within the body. Rupture of internal abdominal organs such as the spleen, kidney and liver can occur with surprisingly little to show in the way of external injury. A fractured thigh bone can pierce the main artery of the leg and cause lethal internal haemorrhage without a drop of blood being visible. In all these cases diagnosis is urgent, followed by emergency blood transfusion if the brain, and hence the patient's life, is to be saved.

Means of detecting the presence of severe haemorrhage without seeing any blood are taught in First Aid Classes as the Signs of Haemorrhage. They are in fact manifestations of the reactions of the body in its attempts to save the failing brain, and are therefore the same as the signs of shock. The main ones are a rapid, feeble pulse, getting more rapid and more feeble as time goes on in a desperate attempt to get the remaining blood to the brain; skin pallor caused by constriction of blood vessels near the surface so that the blood which remains is shunted to the brain away from the less vulnerable skin; and finally, just before death, restlessness and air hunger.

A word of warning about the First Aid treatment of shock due to heart attack (coronary thrombosis). These patients must be transported at complete rest, but many of them react very badly to being made to lie down, since they have great difficulty in breathing in this position. Transport them relaxed, in a sitting position, supported by a large comfortable back rest.

It cannot be too strongly emphasised that with haemorrhage and shock, as with so many First Aid emergencies, the importance of protecting the brain is paramount.

Asphyxia.

The previous section was concerned with maintaining an adequate supply of blood to the brain. This is needed in order to supply the brain's only possible fuel—glucose—and the oxygen with which to burn it. Many different circumstances can conspire to reduce the oxygen content of the blood, and the result in each case is asphyxia. Normally, air is taken into the lungs through the air passages and brought into contact with all the circulating blood. It diffuses from the lungs into the blood, where it enters into a special relationship with the pigment of the red cells—haemoglobin. At the same time, the waste gas carbon dioxide enters the lungs from the blood and is breathed out. The revitalised blood is passed through the heart to build up sufficient pressure to drive it into all the tissues of the body, and in particular into the brain. A special system in the brain—the respiratory centre—controls the complicated machinery of respiration and is itself, of course, kept alive by the products of the very mechanism it controls. This mechanism consists of all the muscles of respiration—those which lift the ribs, the diaphragm and many other so-called accessory muscles. They all have to be finely co-ordinated by means of nerve impulses which begin in the brain, pass down the spinal cord and out to the muscles. Information of many kinds comes along sensory nerve pathways to the respiratory centre so that breathing can be automatically adjusted to the changing needs

of the moment. In order that life may continue there must be:

(1) a functioning breathing mechanism to revitalise the blood; and

(2) a circulation to carry the revitalised blood to the brain and other tissues.

In many cases when breathing stops and unconsciousness supervenes as brain function is depressed, the heart will go on beating for some time longer. The aim of First Aid is to restore the breathing by artificial respiration *before the heart stops*. Once the heart stops—and it eventually does so abruptly and without warning—the brain is dead within the usual few minutes unless *both* the heart and the breathing are restarted; and this is a very much more difficult proposition than artificial respiration alone.

For these reasons, a patient whose breathing has stopped must have it started again without any delay. Here, as in the case of severe haemorrhage, it is no use telephoning the doctor or even putting the patient in an ambulance. The First Aider must act himself, because he is on the spot and the only one in a position to save life. Both actions require elementary First Aid training, and even school children can accomplish them if they have been well taught.

Asphyxia is the name given to a failure of the oxygen supply to the brain and is due to a breakdown in some part of the complicated breathing mechanism outlined above. One of its chief causes is a blockage of the airway by (*a*) solids or (*b*) liquids. Any foreign body of the right shape and size will block the airway, as also will the tongue in the unconscious patient. Remember how much more easily the child's airway can become blocked because it is so much smaller. Blockage by a liquid, is of course, drowning. Remember that if a patient drowns in the entire ocean, it is only about half a cupful which is doing him any harm—as it only takes this amount to fill the airway. The same goes for the amount of tea, or vomit, required to kill an unconscious patient if it gets down the " wrong way "—as it will unless someone prevents it.

Another very common cause of asphyxia is carbon monoxide poisoning. Carbon monoxide is a lethal component of car exhaust fumes, incompletely burning and badly ventilated fires and stoves, and domestic coal gas. One of the inconvenient properties of haemoglobin is that it combines with carbon monoxide very much more eagerly than with oxygen. Prolonged contact with even a very slightly contaminated atmosphere can build up a concentration of carbon monoxide in the blood which will prevent the blood from carrying sufficient oxygen—and this is in fact how it kills. It takes a very short time for this to happen if the atmosphere is heavily contaminated. Remember the danger of even a very slight leak of the gas either in the kitchen, or into a car from a faulty exhaust pipe or silencer. Many elderly people die of coal gas poisoning every day because their sense of smell is poor and they do not detect the leak.

Other causes of asphyxia are lack of oxygen in the atmosphere, as occurs at high altitudes; crushing of the chest so that the ribs cannot move; paralysis of the muscles of breathing by interference with their nerve supply, usually in First Aid, as a result of a broken neck and consequent damage to the spinal cord (poliomyelitis can occasionally produce the same effect by attacking the nerves just before they leave the spine); and depressing the respiratory centre in the brain, most commonly nowadays by barbiturate poisoning.

The only really effective method of artificial respiration, which all members of any civilised community should be able to carry out, can be learned in half an hour at a good First Aid class. This is the direct, mouth-to-mouth method, sometimes dramatised by journalists as the " kiss of life." The method is taught with the aid of models and cannot be satisfactorily learned by only reading about it.

In discussing asphyxia, we have again had to consider the particularly vulnerable situation of the brain.

Fractures.

Broken bones are not the most serious possible consequences of injuries causing fractures. It is usually more to be feared that further damage will be done by the broken ends of the bones to tissues and organs in the neighbourhood of the fracture. The First Aid treatment of immobilising the part before transporting the casualty is designed to avoid this.

Six types of fracture are commonly taught, but some of them may co-exist in the same injury and the division is only for descriptive purposes. In addition there are two special fractures of the skull.

A " simple " or " closed " fracture is where only the bone is broken, without damage to surrounding tissues and without a wound. A " compound " or " open " fracture is one in which air, and hence germs, can get at the broken bone. This may be through a wound, in whose depths lies the broken bone; or the bone may have been pushed out through the skin; or a bullet track may lead down to the fracture. All these are examples of compound fracture and the great danger is that the bone will become infected. Even now that infections are less feared than before the days of antibiotics, it is still a grave matter for bone to get infected. However the antibiotic is given, we rely on the blood supply to carry it into the infected tissue, and bone has only a very small blood supply. If the infection is not successfully treated it can smoulder for a long time and become a " chronic osteomyelitis " which might ultimately necessitate amputation of the limb—and all because the original fracture was compound or open.

A " complicated " fracture is one in which the broken ends of the bone have damaged some important organ or tissue in the region. For example, a complicated fracture of the ribs is one in which the lung tissue, close behind the inner surface of the rib, has been pierced, and the patient will be coughing up small amounts of bright red, frothy blood. A " comminuted " fracture is one where the bone is broken into several pieces, and an " impacted " fracture is one in which the broken ends have been driven into each other and are firmly impacted. Finally a " greenstick " fracture occurs sometimes in children because their bones are not brittle and do not always break clean across. They partly break like a green stick.

" Depressed " fracture of the skull is where the vault of the skull has been struck and dinted. Many problems arise, since the brain is inevitably compressed and no dressing of the accompanying wound should be allowed to press on the brain. The dangers of infection here are not only to the broken bone, but to the meninges covering the brain, causing meningitis.

Fractured base of skull often passes through that part of the base through which the internal ear channel runs. Thus it frequently results in blood, or cerebrospinal fluid, or a mixture of both, emerging from the ear. The gravity of this fracture lies in the severity of the impact necessary to produce it, which will probably have also caused great destruction of delicate brain tissue. The outlook is usually very poor.

Remember that most casualties with fractures will require a general anaesthetic on arrival in hospital so that their fracture can be set in plaster or otherwise treated. Avoid giving them things by mouth such as drinks, which will mean a three-hour wait before anaesthetic can be administered.

Burns and Scalds.

The severity of a burn or scald depends largely on its surface area. If a patient dies of a burn, the cause of death is either infection or shock,

the latter being due to fluid loss from the surface. Both hazards depend on surface area, since the bigger the surface the more germs are able to enter, and the more fluid can be lost. It follows that the small burn on the hand or arm is seldom a threat to life, however deep the injury; and we shall therefore confine our attention to the larger burns of the whole surface of the limb or trunk. Smaller bodies have a relatively larger surface area, and so a burn of the surface of a child's limb or trunk represents an even greater risk from fluid loss than a corresponding burn in the adult. Everyone has seen the fluid form in the blister of an ordinary small burn. It comes from the fluid part or "plasma" of the blood stream and the loss into such a blister may amount to a thimbleful. This will not hurt anyone. But the loss of similar fluid from the surface of a large burn may amount to many pints. The resultant shock will be partly due to this fluid loss from the blood stream resulting in a reduction in blood supply to the brain. Thus shock from burns has common features with shock from haemorrhage, and it is treated similarly, by transfusion. This time it is not a transfusion of blood but of plasma or some plasma substitute. In practice it is not only water that has been lost but a number of important chemicals dissolved in it as well, so that transfusion solutions have to contain sufficient of each individual substance to restore the deficit. The arrangements for replacing the lost materials are complex and urgent; every bit as urgent as after a haemorrhage and for the same reason. The brain cannot be left too long in need. In general, the First Aid treatment of burns of large surface area is to keep them clean with a dry dressing and get them very quickly to hospital. Life-saving treatment by transfusion cannot start until they arrive. The only permissible delay is in the case of burns caused by corrosive chemicals which must be thoroughly washed off before transport, so that they do not continue to burn the patient on the way.

Unconsciousness.

It is not sufficiently appreciated that the dangers of being unconscious can often far outweigh the dangers from the cause of the unconsciousness. For example it is known that as many as half the deaths from head injuries are due to the airway becoming obstructed and not to the injury itself. The most important thing in managing the unconscious patient from any cause is to preserve an airway. Particularly if the patient is lying on his back it is likely to get blocked:

(*a*) by his own tongue as the lower jaw sags backwards;

(*b*) by his dentures (so remove them);

(*c*) by vomit; and

(*d*) by anything anyone may be tempted to give him by mouth.

Nothing whatever should be given by mouth in any circumstances to the unconscious patient, since he cannot swallow and it will inevitably go into his lungs.

Many of these dangers can be very much reduced by not having him on his back. Place him instead in the semi-prone position: half on his side, half on his front, with the upper leg drawn up to prevent him from rolling about. In this position the head will be inclined downwards. The jaw will tend to sag forwards and the tongue with it, away from the back of the throat. Any vomit will also come forwards. If the tongue does get in the way of the breathing the airway can usually be cleared by bending the head backwards as far as it will go and pushing the whole lower jaw forwards, by pushing from behind the angle of the jaw on both sides.

DRUG ABUSE AND DRUG DEPENDENCE.

This section of earlier editions of *Pears* was simply called "Addiction." This word is still much used, but is gradually being replaced by the terms in the present title, because ideas about the nature of the problem and methods of dealing with it are changing. Addiction is a word that conjures up rather 19th century ideas in the minds of readers: opium dens, inscrutable orientals, Sherlock Holmes injecting himself with cocaine—basically a phenomenon of foreign origin, rather frightening if its implications were not literary rather than factual, and not of great significance in Great Britain.

Drug Abuse.

It is now realised by doctors, research scientists, social workers, and the police—if still not by society as a whole—that the truth is quite different. The *abuse* of drugs in this country is at present of large proportions, increasing rapidly and showing no signs of diminishing. It is responsible each year for thousands of deaths by suicide and by accidental overdosage; for an enormous but virtually unmeasurable amount of private suffering; and for the loss to society, in terms of reduced working efficiency, of millions of man-hours every year. It has nothing to do with opium smoking which was never in any case more than the eccentricity of the few. Opium is virtually unused in medicine these days and the amount of smuggling, always small, is now negligible. The problems today arise chiefly from the misuse of drugs given by doctors for their effects on the central nervous system—the pain-killers, sleeping pills, "stimulants," and "tranquillisers."

Drugs and Medicines.

To the doctor, any substance is a drug that can be introduced into the body from outside, and that is capable of producing some detectable effect. Most such substances have a beneficial use. They are "medicines," and as such are given by doctors in suitable cases. Others, for example, nicotine (in cigarettes), alcohol (in beer, wine, or spirits), and carbon monoxide (in coal gas), are of doubtful benefit and of certain harm and are used by doctors, if at all, only under certain very special and usually experimental conditions.

Medicines may be classified under four main headings. First, there are those like quinine, or penicillin and other so-called antibiotics, that actually cure diseases by eradicating the organism (bacteria or other parasites) that cause disturbance of normal bodily function. Second, drugs such as insulin or the steroids overcome in the unhealthy the lack of some necessary substance a healthy body manufactures for itself: they must usually continue to be given for life. Third are the drugs which relieve the signs of disease—for example, there are many new drugs that lower the blood pressure or increase the output of urine—without being able to put right the disturbed basic situation which is the cause of the trouble. Fourth are drugs to relieve the patient's symptoms—which make him feel better, less breathless, take away his pain, help him to sleep, and so on—although we seldom know why they are able to do this. Indeed, in many cases we suspect that they are acting mainly as a token of help from doctor to patient, and so encouraging his body to fight a more successful battle on its own behalf. (There is in fact a fifth class of drugs, which includes the majority of those on the market at any time, the members of which are devoid of any action whatsoever except that of enriching those who manufacture and sell them; but we are not concerned with these at the moment. They constitute a related, but different, kind of problem.)

There is no doubt that the genuine advances in beneficial drugs during the last thirty years have been enormous; but the very successes of the penicillins, tetracyclines, antimalarials, hormones, and so on have bred in the public and in the medical profession itself an attitude of uncritical wonder. There have been relatively few drugs in the first and second categories mentioned above: and in the field of mental health, the importance of which is now so rightly emphasised, there are virtually none. Yet drugs which act

upon the brain are often received as if they were curative although they may pose fresh problems rather than solve the old. Thus, although there are many drugs which act upon the mind, few do this in any fundamental sense: they relieve pain and anxiety, bring sleep and lessening of stress, and may allow the patient to recuperate himself during the relief they provide. But often this deeper change does not occur—sometimes because the doctor has not clearly seen his part in helping to bring it about—and then the symptomatic relief may come to be sought for its own sake.

New and old drugs are still prescribed for their effects upon the mind—less so now than even a few years ago, before the thalidomide disaster—without sufficient attention to possible long-term dangers, of which there are in effect four.

Dangers of Long-term Medication with Drugs acting on the Brain.

1. *Toxic effects.* Drugs which act upon the nervous system, like any others, have characteristic toxic or unwanted effects of their own (incidentally, these may become apparent rapidly; even, on rare occasions, after only a single dose). Such effects may have little or nothing to do with the desired effects for which they are being prescribed and taken. For example, it has only come to be realised quite recently that aspirin is liable to cause bleeding, which is occasionally serious, from the lining of the stomach in a large proportion of people who take aspirin regularly; or that phenacetin, another substance very frequently present in pain-killers that can be bought from chemists without prescription, leads (after prolonged use) to kidney damage. Some drugs may cause rashes and other allergic reactions in susceptible subjects; and jaundice, fainting, tremors, and motor disorders are known to occur in some patients taking a variety of other drugs.

2. "*Rebound.*" The body works in such a way, over a variety of its activities, that it tends to return to a "neutral" position after it has departed from this for any reason. For example, over-eating tends to be followed by a lessening of appetite, at least for a time; the runner makes up for his air-deficit during the race by breathing more deeply thereafter; and if, at rest, you breathe for a time more rapidly and deeply than you need, this period will be followed by one in which you breathe *less* often than usual until the balance is restored. These illustrations—and there are others—have nothing to do with drugs: but in a similar way, it seems that if a continued pain, or an unpleasant emotional state such as anxiety or depression is changed into its opposite, or removed altogether by the use of a drug, the prior state may return with increased force when the drug is no longer taken. The "rebound" phenomenon, naturally, encourages the patient to take another dose, and so on.

3. *Habit formation.* This alternation of mood-changed-by-drug with the disturbed mood itself leads to the habit of taking the drug. The patient comes to rely upon it and to take it anyway, even before the unpleasant state has returned. At this stage he is said to be "habituated": he has a psychological need for the drug, and later may become disturbed at the possibility that it will not be available when he needs it. This might not matter so greatly, if it were not that continued use of drugs in this way has physical consequences as well.

4. *Tolerance and habituation.* The body also tends to restore its own balance when drugs are given, too. It "learns" surprisingly quickly how to deal with substances with which it has never before been confronted, so that it eliminates subsequent doses more and more quickly and completely. Thus the effect of each successive dose is smaller and lasts for progressively shorter periods of time. To counter this, the patient tends to increase the dose: and the vicious circle continues. At this point he has become physically dependent upon the drug: and he may suffer physically—sometimes so severely that he dies—if supplies are not continued.

As he increases the dose in this way, so his tolerance of its effects increases, to such an extent that after prolonged use he may be taking doses of a drug that are five or ten times greater than those which will kill somebody not dependent upon them in this way. It sometimes happens that a patient develops a renewed craving at some point after a course of treatment, in which the dose of drug has been reduced without removing the underlying cause of his dependence. He may then obtain and use the dose he habitually took before treatment, not knowing that his body will have lost its tolerance of such doses. That dose is now as high for him as for any other person and so may be lethal. There has been a number of deaths for this reason.

Factors in the Causation of Dependence.

The risk of becoming dependent upon a drug is governed by three main factors: the drug itself, the personality of the individual who takes it, and the circumstances in which it is taken. Most adults have taken alcohol at one time or another, unless it is against their code to do so; yet *relatively* few are dependent upon it (relatively few, but many too many: perhaps half a million in the United Kingdom alone). Many of us have had morphine or some other strong pain-killer for medical reasons, without becoming dependent upon it (whatever so-called addicts say, it is extremely rare for anyone to become dependent on an opiate because he was introduced to it in a medical setting). On the other hand, if we start to take such a drug "for kicks"—as more and more people, particularly teen-agers and young adults are doing—it is extremely probable that we shall become dependent upon it, and sooner rather than later at that. It is also probable that each one of us would become dependent, were he obliged to take it regularly, for long enough, and in sufficient dosage. Thus, although there are personalities—psychopathic, immature, or unstable—that are more prone than others to become dependent if they are exposed to the drug, there are also drugs that are more likely than others to cause such dependence no matter to whom they are given. The extent of the dependence will vary: with some, it is never physiological but remains psychological (but not the less real or disturbing for that). Also, the rate at which dependence develops may vary; and the picture presented by the dependent subject—the extent to which his normal life is impaired, or to which he becomes dangerous to himself or others—varies as well. In a very much oversimplified way, some of these relationships will now be summarised for certain substances.

Heroin, morphine and cocaine are usually injected. Barbiturates (sleeping pills) and Amphetamine ("Benzedrine") are tablets or capsules, and Marihuana ("reefers," hashish) is smoked in cigarettes. Heroin and cocaine are now usually taken together. Combinations of drugs often act differently from their individual constituents and patients dependent upon them are even more difficult to treat. Barbiturate and amphetamine, also, are often mixed (as in "purple hearts"). There is considerable *psychological* dependence on heroin, morphine, cocaine, and amphetamine, but much less with marihuana. *Physiological* dependence is great with heroin and morphine, less with barbiturates, alcohol, and amphetamine in that order, and virtually nil with cocaine and marihuana. Personality plays a greater part in initiating dependence on alcohol, marihuana, and barbiturates than with the others. Heroin, cocaine, and morphine are the cause of more antisocial tendencies in dependent people than alcohol, barbiturates, and amphetamine. The chief danger of marihuana (mere possession of which is illegal) seems to be that the search for it will lead the searcher into localities where his risk of exposure to even more dangerous influences is greatly increased. It is thus some-

times argued that if it were legal to consume marihuana, the number of young people who yearly become dependent upon the other more dangerous drugs would in fact decrease. There is as yet no evidence for or against this proposition. The number of drug dependent people in U.K. is rising fast for heroin and cocaine. This number is very large for alcohol, and is increasing in the case of barbiturates and marihuana. Very few people are dependent on morphine, and the number is not growing.

Treatment.

Exhortations, imprisonment, and other moralistic or legalistic approaches are useless. Treatment of any person dependent upon a drug is a matter for a qualified psychotherapist. It is liable to be time-consuming and frustrating for patient and doctor, and it is frequently unsuccessful. At present, there are too few specialists or centres where treatment can be obtained, although it is to be hoped that this situation will change as the problem is increasingly seen by our society to be of exceptional gravity.

When there is little or no chance of cure, prevention is certainly the best treatment. Drugs should only be taken on the prescription of a doctor: and the patient should remind him from time to time, if this be necessary, that he would like to dispense with his drugs as soon as the doctor thinks it possible. It should also be remembered that there is often no need to reach for the aspirin (or any other drug that anyone can buy from the chemist without prescription) at the first sign of a headache—or to reach for it at all to help one sleep or relax, for which purpose such drugs are in any case pharmacologically useless. A wait for ten minutes is good discipline, and will frequently resolve the problem to an extent that makes a drug unnecessary.

DISEASES OF THE BLOOD.

INTRODUCTION.

There are about eight or ten pints of blood in the adult human body. Its main function is to transport nutrient materials to all the various tissues and to carry waste products of tissue activity to organs such as the lungs, kidneys, and liver for disposal. It also helps to maintain a constant chemical environment for the body cells, some of which would be very disturbed in their function if the correct balance of organic and inorganic chemicals were not maintained. The blood also serves a protective function in fighting disease, either with certain of the white cells, or by means of immune antibodies dissolved and carried in the plasma.

A little more than half the volume of blood is the fluid plasma, in which are dissolved all the nutrient materials, organic and inorganic chemicals, hormones and large quantities of protein. The remainder consists of red cells, white cells, and some particles which are not really cells, called platelets. In every cubic millimetre of whole blood, or in every droplet the size of a pin head, there are about 5 million red cells, between 5,000 and 10,000 white cells, and 200,000 platelets as well as half a cubic millilitre of plasma. The red cells suffer a great deal of wear and tear as they are hurled round the circulation, and they only survive for three or four months. There is a red cell factory in the bone marrow which replaces them at exactly the rate they are destroyed, and you have made very many millions of new ones while you have been reading this single paragraph. The function of the red cells is to carry the oxygen from the lungs to the tissues, and to play an important part in carrying the waste gas, carbon dioxide, in the reverse direction. A shortage of red cells, and hence of their oxygen-carrying pigment, hæmoglobin, is called anæmia; an excess is called polycythæmia.

There are five kinds of white cells or leucocytes: neutrophils (or polymorphonuclear leucocytes), eosinophils, basophils, lymphocytes, and monocytes. The first three are quite actively motile, like amœbæ, and are capable of ingesting bacteria and other particles by "phagocytosis." There is a great increase in the number of neutrophils (a leucocytosis) during bacterial infections and other inflammatory conditions like appendicitis. Eosinophils are found in larger numbers than usual in allergic conditions like asthma, and in infestations by worms and other parasites, but we do not know why this should be. Lymphocytes are concerned with the manufacture of antibodies. In some infections, particularly tuberculosis and viral infections, there are fewer white cells than usual (leucopenia). Pus consists of the dissolved remnants of inflamed tissue and many dead neutrophils which have become casualties in the battle against infection. It also contains surviving bacteria, and as such is a source of further infection.

Platelets are curious particles, smaller than any of the cells. They are little pieces broken off certain special bone-marrow cells which produce them. They have a role in the stemming of blood loss after injury, partly because they are sticky and adhere to one another and to broken blood vessels and help to plug the open ends of damaged vessels; and partly because they contain a great deal of a substance (thrombokinase) which is necessary to the clotting mechanism of the blood.

Hæmatology, as the study of blood and its diseases is called, is a very complicated subject and only a brief general account will be given here. Diagnosis is usually made by taking small samples of blood (or of the bone marrow where blood cells are made), counting the numbers of the different cells and examining their appearance under the microscope. We shall briefly consider the main diseases involving red cells, white cells, and platelets.

Red Cell Diseases.

These are of two main groups leading to a shortage of red cells (anæmia), or an excess (polycythæmia). The former is much the more common and there are many different kinds. In all of them the shortage of red cells results in a depletion of the capacity of the blood to carry oxygen. This means that the heart must work harder to send more blood than usual to the tissues, and even so the tissues will often go short. The patient will be persistently tired and listless, and if the anæmia is severe the action of the brain and heart will be seriously impeded, even leading to fainting, cardiac pain, and breathlessness on exertion. All these symptoms, however, can be caused by many other conditions. The only way to be sure they are due to anæmia is by a proper examination of the blood, and even this will not lead to the truth if the picture has been spoilt by the patient taking iron tonics and other remedies of his own accord. Therefore do not dose yourself with tonics, in case you really have anæmia. You may make it impossible to arrive at a proper diagnosis later.

Hæmorrhagic Anæmia. Anæmia, a shortage of red cells, may be due to a variety of causes, singly or in combination. One very obvious cause is loss of blood, or hæmorrhage. Following the sudden loss of a pint or two of blood or more, the red-cell-producing bone marrow "factory" will step up its production; but even if it is adequately supplied with all the raw materials such as iron, it may well take many weeks to build up the numbers to normal. A very severe degree of hæmorrhagic anæmia is usually treated by blood transfusion. Milder degrees can be treated by taking extra iron, often over a long period of time. The supply of iron for making new red-cell pigment is nearly always the bottle-neck which limits production. Hæmorrhagic anæmia can commonly occur, however, without a sudden severe hæmorrhage. From what has been said about the constant replacement of red cells as they wear out, it must be obvious that even if there is only a slight failure to keep pace with the numbers lost, several

months of such a failure can eventually deplete the numbers to the level of very severe anæmia. This situation is common when small amounts of blood are being continuously or repeatedly lost, and here again it is a shortage of dietary iron which is the usual cause of the failure to replace the lost red cells. Normal menstrual loss in women and girls whose diet is on the border-line of iron deficiency is a common cause of progressive tiredness and lack of energy. Where the menstrual flow is heavier than usual, or where it is frankly excessive in older women due to the various common gynæcological disorders, serious anæmia is surprisingly common. During pregnancy a great deal of iron is lost by the mother to the baby, and this, together with the inevitable blood loss at delivery, often makes for a very tired mother indeed, just at the time when there is an enormous amount of work to be done to manufacture milk and attend to all the extra household tasks of baby care. For these reasons it is almost routinely advisable to build up stocks of iron throughout the pregnancy by remembering to take the pills provided. Men as well as women can lose small amounts of blood continuously in later life from gastro-intestinal conditions such as piles, ulcers, and tropical infestations such as hookworm; and here again the anæmia may be just as severe in the long run as that which inevitably follows a sudden, massive hæmorrhage. One extra word of warning. Do not assume because you are pale that you are anæmic. Pallor is a very poor guide, because it is dependent on so many other things, like the blood vessels in your skin, and its thickness and translucency. Nothing but a blood test (which is so easy for your doctor to do) can really tell you if you are anæmic. And if your anæmia is due to a blood-losing condition, then that too must be treated. So do not be tempted to treat yourself, and never delay seeing your doctor about any excessive or unexplained bleeding, from any source.

Hæmolytic Anæmia occurs when for any reason, there are more blood cells than usual being destroyed in the body. This may be because the cells are abnormally fragile, or because normal cells have been attacked by something to which you are allergic, or rarely because you have become sensitive to your own red cells. Sometimes unborn babies have severe hæmolytic anæmia, due to an incompatability of blood group (Rh factor) between the mother and the baby, and the same sort of thing happens if incompatible blood is given by mistake in blood transfusion. Up to a point, in mild hæmolytic anæmia, the bone marrow can keep pace with the increased loss of cells, but beyond this point anæmia develops. After incompatible blood transfusions a very dangerous situation results from the effects of the destruction of red cells and the liberation of their products into the blood. One form of jaundice is often produced in hæmolytic anæmia, the patient becoming yellow because of the breakdown products of red cells circulating in excess as bile pigments. These latter are normally always present to a small extent due to the normal, comparatively small, rate of destruction of effete red cells

Aplastic Anæmia is the term given to anæmia due to a virtually total failure of the bone marrow red-cell factory. Sometimes this occurs for no obvious reason. It is sometimes due to a heavy dose of radioactivity or X-rays knocking out the cells of the "factory." It may even be due to cancer cells growing in the bone marrow cavity and not leaving sufficient room for the red marrow cells. It is fortunate that aplastic anæmia is very rare, because it can only be treated by blood transfusions every few weeks for the rest of the patient's life. Very occasionally there have been exceptions to this rule, when the patient's marrow has re-awakened for no apparent reason and suddenly begins to make red cells again.

Pernicious Anæmia. This is a fairly uncommon anæmia, which has a very interesting story. The processes by which red cells are manufactured are many and complex, and depend, like so many other bodily activities, on the supply of a vitamin containing cobalt, called vitamin B_{12}. This is nearly always present in more than adequate quantities in the diet, but in order for it to be absorbed from the intestine, there must also be a substance called "intrinsic factor" which is normally made by the lining of the stomach. People with pernicious anæmia have suffered a degeneration of the lining of their stomachs, probably because, for some reason, they have become "sensitive" to this part of their own tissue. This kind of civil war within the body is known as an "auto-immune" disease, and is comparable in type with some forms of hæmolytic anæmia. In other words they destroy their own stomach lining, fail to produce "intrinsic factor," and as a result fail to absorb vitamin B_{12} into the body. Faced with a failure in the supply of this essential substance, the bone marrow produces too few red cells, and the few that are produced are deformed, much too large, and very fragile. In addition to its role in blood formation, vitamin B_{12} is essential to the normal functioning of the spinal cord, and in long-standing cases of untreated pernicious anæmia, there is often a resulting neurological disability.

The cure for pernicious anæmia was discovered about forty years ago, and is a triumph for the scientific investigation of the causes of disease. While treating anæmic dogs, an American scientist named Minot discovered that eating raw liver in large quantities produced a tremendous improvement. Patients with pernicious anæmia were then made to eat vast quantities of raw liver—about one or two pounds a day—and were found to get better, whereas previously they had inevitably died. Raw liver is, of course, very unpleasant to eat, and after a few years it was found possible to prepare crude extracts for injection. Injection had the great advantage that no absorption difficulties arose, and much less liver could be used. Biochemists then began the enormous task of trying to find which of the thousands of substances in liver was the vital factor, and after many years of painstaking chemical fractionation of liver and trying out the various fractions as a cure for the disease, vitamin B_{12} was discovered. The pure substance is one of the most powerful substances known, being active in amounts as small as millionths of a gram. Nowadays pernicious anæmia is treated by small occasional injections of the vitamin, whose other name is cyancobalamin.

Polycythæmia. Too many red cells per cubic millilitre of blood can be found without there being an increase of the total number of red cells in the body. This occurs in dehydration, when there is a loss of plasma without a comparable loss of cells, and is called hæmo-concentration. Alternatively, the bone marrow can manufacture more cells than usual as a response to living for long periods at high altitudes. The beneficial result can be that the blood can carry normal amounts of oxygen, even though the supply (in the rarefied air) is reduced. Finally there is a red cell disease, analagous to leukæmia (*q.v.*) in which the bone marrow factory gets out of control and produces too many cells with no beneficial results. The number in the blood can be double the normal and the blood becomes so thick that the heart has difficulty pumping it round the body. This disease (*polycythæmia rubra vera*) used to be treated by repeatedly bleeding the patient to reduce the numbers. It is now treated very successfully with carefully judged amounts of radioactive phosphorus or certain other "anti-mitotic" chemicals which reduce the rate of multiplication of bone marrow cells. Care has to be taken not to knock them out altogether, in which case aplastic anæmia or agranulocytosis (*q.v.*) could result.

White Cell Diseases.

These are fortunately much rarer than diseases involving red cells, and are usually much more to be feared.

Agranulocytosis. In this condition the number of those white cells which are responsible for phagocytosis of bacteria falls precipitously. The result is that one of the main bodily defences against infection fails, and the patient may die from an overwhelming invasion of germs and the accompanying high fever. The usual cause is abnormal sensitivity to certain drugs, often those which are in widespread use and only give trouble in the occasional case. One example among hundreds is the antibiotic chloramphenicol which specifically kills typhoid bacteria and is used for that purpose. It is believed that about one case in 60,000 becomes sensitive to it and agranulocytosis often fatally follows. The fact that almost any drug *can* do this to some people and yet be quite safe for the majority, is one good reason not to dose yourself unnecessarily with over-the-counter medicines.

Leukæmia. This is a cancer of the white cells, in which the normal rate of production of any of the white cells gets out of control, leading to a pile-up of abnormal cells at the site of production (bone marrow, lymph nodes, and spleen) or in the blood, or both. In spite of an increase in their numbers, their abnormality renders them unable to combat infection; sepsis and fever result. It is known that this kind of cancer can be caused by the effects of ionizing radiation on the white-cell factory, and it is certain at least in animals, that viruses can also be responsible. Survivors from the atomic explosions in Japan have subsequently suffered from leukæmia far more commonly than the rest of us, as have doctors, nurses, and patients who have been over-exposed to X-rays. At the time of writing, leukæmia is still a uniformly fatal disease, although patients may sometimes survive many years. Their remaining time can nearly always be made more comfortable by various forms of treatment, and one day a cure will be found by the research workers devoting their time to its study. It is difficult not to get very impatient with the slow rate of progress of these studies, particularly when caring for children and young people whose lives are inevitably ended by the disease. The solution, however, as with other forms of cancer, probably depends on the understanding of the nature of life itself, and as long as biological research remains short of the relatively small amounts of money required to tackle these problems at reasonable speed, we have no right to be impatient, except with our elected leaders who spend far more than is needed on less important things.

Hodgkin's Disease, Lymphosarcoma, and Reticulosarcoma. These are cancerous diseases in many ways similar to leukæmia, in which the cancer process involves cells of the so-called reticulo-endothelial system. Such cells are principally in lymph nodes (which used to be called lymph glands) and the spleen. Hodgkin's disease is named after one of the more illustrious pathologists at Guy's Hospital who first described it nearly a hundred years ago, and whose early specimens of affected lymph nodes are still preserved there; is an even greater puzzle than leukæmia. There are all grades of severity, and although many patients die within six months, many survive much longer, even for twenty years in some cases.

Hæmorrhagic or Bleeding Diseases.

Whenever blood vessels are damaged by injury, there is a remarkable series of mechanisms which automatically come into operation to stem the flow of blood. There is a constriction of all the smaller vessels in the locality. Platelets stick together and release substances which help the vessels to stay constricted as well as others necessary to blood clotting, and yet others which help to bind the clot tightly together. Later, materials appear to prevent too much clotting, and eventually the clot is removed altogether as healing proceeds. There are some very complicated diseases of this blood-conserving mechanism which can lead to abnormal bleeding, sometimes beneath the skin to produce bruising or even smaller leaks; sometimes leading to a greater loss of blood, particularly following a wound. In some kinds of *purpura* (bleeding tendency) the blood vessels are the cause of the trouble, having become fragile and leaky for a number of reasons. This happens in old age (*senile purpura*), in scurvy, or vitamin C deficiency, as an occasional accompaniment to infective diseases, or as an immunological effect on the lining of blood vessels when the patient becomes sensitised to certain substances (*Schönlein-Henoch* or *anaphylactoid purpura*). The latter often follows a streptococcal sore throat, just as rheumatic fever and acute nephritis do; and as well as the purpura there may be joint pains and nephritis. Just as almost any drug or chemical will cause agranulocytosis in some people, so it can also cause anaphylactoid purpura.

Purpura may also be due to a lack of platelets, known as thrombocytopenia (a shortage of thrombocytes or platelets). This can happen if the bone marrow factory is depressed, since this is where platelets too are made. It is therefore a common accompaniment of leukæmia or aplastic anæmia. Or there can be increased destruction of platelets in some diseases of the spleen. Platelets normally last eight to ten days, but their life-span can be shortened in heart failure, and following massive transfusions, or often for no apparent reason ("idiopathic" thrombocytopenia), when removal of the spleen can sometimes help.

Finally, defects of the *clotting mechanism* will lead to a bleeding tendency, and since the mechanism itself is very complex, so is the variety of things which can upset it. The liver provides the blood with many of the substances required for clotting, so it is not surprising that a clotting defect commonly accompanies liver disease. One necessary substance for blood clotting is called "anti-hæmophilic factor" and is missing from people who have inherited the disease *hæmophilia*. These unfortunate people may die of hæmorrhage from quite small cuts or minor surgical procedures like tooth-extraction, and although it is possible to prepare antihæmophilic factor, it is not yet possible to give continuous, life-long treatment with it. A new drug, aminocaproic acid, which prevents natural clots from dissolving, is now used to enable dental treatment, with the saving of much fresh blood transfusion which was formerly necessary.

DISEASES OF THE HEART AND BLOOD-VESSELS.

INTRODUCTION.

The heart consists of about three-quarters of a pound of muscle, which makes up the walls of its four chambers. Anatomically the human heart closely resembles the sheep's hearts to be found in a butcher's shop. Indeed it would be an instructive exercise to dissect one of these in the order described below, since there is no other way of properly appreciating what the chambers, valves, etc., are really like. There are two quite separate pumps in the heart—one on the owner's right (or on your *left* if you are looking at the front of someone else), and one on his left. The right heart collects spent, deoxygenated, "venous" blood which returns there from the whole of the body, and gives it the comparatively small push required to drive it through the adjacent lungs. The left heart collects the revitalised, oxygenated "arterial" blood as it trickles away from the lungs, and gives it the enormous push required to build up the arterial blood-pressure, so that it can be forced through all the tissues of the body. As may be expected, the right heart chambers have much thinner walls than the left, since their muscle has much less work to do. This will help you get your bearings with the sheep's heart. The tip, or apex, is the lowest part. The thick-feeling side is the left, the thin the right; and the great vessels are at the top.

The upper chamber on the right, or right atrium, has two large openings into it through which all the spent blood arrives from the upper and lower great veins (the superior and inferior venae cavae). Cut open the thin wall of the right atrium with scissors between these two holes to lay open the interior of the chamber, noting the "auricle" or

" dog's ear " that forms a small cul-de-sac. The whole chamber is sometimes, inaccurately, called the auricle. You should be able to push a finger downwards into the lower chamber—the right ventricle—through a communicating hole guarded by the three thin cusps of the *tricuspid valve*. These will not obstruct your finger, since they are designed to permit blood flow in the same direction. When the atrium is full of blood, it squeezes its contents through the tricuspid valve into the right ventricle; and when, a split second later, the ventricle is full and contracts, the three cusps come together to prevent the blood from flowing backwards into the atrium again. Instead the spent blood is driven onwards through the *pulmonary valve* (in the upper part of the right ventricle), through the pulmonary artery, to be delivered to the lungs. The pulmonary valve has three very well-defined cusps which prevent blood from coming back into the ventricle as it relaxes to receive more blood from the atrium before the next contraction or beat. It is possible to pass a blade of the scissors from the opened-out right atrium, through the tricuspid valve towards the tip of the heart, and cut along the right border of the heart through the thickness of the ventricular muscle. Then cut upwards again, passing the scissors blade through the pulmonary valve and open up the *pulmonary artery*. If you have done this successfully you will have followed the path taken by the spent blood through the right heart to the lungs. Notice the thick round bands of muscle lining the ventricle, and notice too that you have not entered the left heart, which has no connection with the right except in some congenital malformations (see later). The same dissection can now be made of the left heart. Open up the *left atrium*, noting its " dog's ear " or " auricle," pass the scissors down into the *left ventricle* through the two rather flimsy cusps of the *mitral valve*. Notice how much thicker is the muscle of the left ventricle, and cut upwards through the three well-formed cusps of the *aortic valve* into the main artery of the body—the *aorta*. The aorta as it leaves the left heart is distinguishable from the pulmonary artery as it leaves the right, partly by the extreme toughness of the aortic wall (it has to withstand so much more blood-pressure); and partly by the entrances or orifices of the two small branches given off by the aorta, just beyond the valve cusps, which go to supply the heart muscle itself with blood. These are the *coronary arteries* which are so necessary for the heart's own survival.

The amount of blood pumped in unit time, or the *cardiac output*, can be varied a great deal, according to the needs of the moment. This is accomplished by altering both the heart rate and the stroke volume, the amount expelled per beat. Every minute, the healthy adult man at rest shifts about ten pints of blood through the heart—an amount equivalent to all the blood he possesses. When exercise is taken, or in response to anxiety or fear, this is stepped up many times, so that the muscles can receive a greatly augmented supply of the materials required for action. The controlling mechanisms which allow these changes to be made automatically are partly organised in the brain by the so-called *cardiac centre*; and partly by local mechanical and chemical stimuli to the heart muscle itself. The cardiac centre is continuously receiving information through nerves about the physical and chemical state of the circulation, and also from the mind; which is partly how certain emotions make the heart beat faster. All the information is integrated, and a cardiac output continuously arranged which is appropriate for current demands.

Cardiac Neurosis. In ordinary circumstances at rest, most healthy people are not conscious of their heart-beat. However, there are many perfectly healthy people whose hearts slip in an extra beat occasionally. Sometimes their owners are aware of this, and become unnecessarily alarmed. Their fear causes palpitations (a pounding of the heart) and the tension mounts. An undue anxiety about the tricks played by a healthy heart sometimes leads people to interpret minor pains in the chest, or even indigestion, as grave symptoms of heart disease, and the consequent anxiety leads to still worse symptoms. If you are one of these worried people, take your worries to your doctor, and let him decide for you whether there is anything wrong. A hundred to one there isn't, and then you will have to find something else to worry about, or better still give up the habit altogether. Many people secretly worry about heart disease and high blood-pressure for years, when very often they are worrying unnecessarily. Even if there is cause for worry, so much can be done for these conditions (as it can for cancer) provided medical advice is taken early in the course of the disease. Remember, too, that the slight feeling of giddiness when you get up suddenly from having been lying down, is often experienced by most normal people; but if you get frightened by it you will begin to breathe more quickly and deeply: and this in itself will make you feel even more faint—and so on.

Heart Failure. When the cardiac output of blood is too little for the requirements of the body, a state of *circulatory failure* has arisen, and when this is due primarily to the heart itself being at fault, it is more properly called *heart failure*. As will be seen, heart failure is not a disease, but the common result of a large number of different diseases. The signs and symptoms produced are caused by two sorts of process: (*a*) tissues of the body have too little blood flow through them and are therefore undersupplied; (*b*) blood accumulates and stagnates in tissues, causing congestion, since the failing heart cannot move forward the amount of blood presented to it in the great veins. Often the left or right side of the heart fails disproportionately. In *left heart failure* the lungs are congested because they are the territory from which the left heart is failing to move blood. The patient has great difficulty with his breathing, and in advanced cases may not be able to breathe when he lies down horizontally, because the lungs become so congested and waterlogged. In *right heart failure* the main veins are congested and other parts of the body become swollen with excess tissue fluid, mainly in the lower parts such as the legs and ankles. This swelling with fluid is called œdema, and in heart failure is only partly due to the mechanics of the failing heart. It is mainly due to a poorly understood retention of sodium in the body, a situation in which excess water is also retained. Whatever the type of heart failure, it is always likely to be a changing condition, since the amount of failure will depend as much on the demands being made as on the state of the heart. For instance, in mild cases at rest when the required cardiac output is small, there may be no signs or symptoms. These may only appear on exertion. Heart failure will be referred to again later under the various conditions which cause it.

Treatment of heart failure is quite logical. It is aimed at correcting the imbalance between supply and demand of blood, and at the removal of the accumulated excess fluid. We can therefore (*a*) reduce the body's demand for blood; (*b*) increase the supply or cardiac output; and (*c*) promote the excretion of sodium and fluid. Demand for blood is reduced by rest, both physical and mental, and by reduction of weight, since obesity (being overweight) is an additional demand on the cardiovascular system. The cardiac output can be increased by administering a " tonic " to the heart muscle in the form of *digitalis*, which is a powerful heart stimulant derived from foxglove leaf. Fluid (and hence salt) accumulation can be helped by restricting the intake of salt and by giving drugs which promote its excretion by the kidneys (diuretics). Very occasionally, very large accumulations of fluid in the legs, abdomen, or thorax, are tapped and drained physically, with needles. These remarks on treatment, as elsewhere in the Medical Section, are of course very general and must not encourage anyone to treat themselves for such a potentially serious condition as heart failure. Even such a simple measure as doing without salt can be practised quite unnecessarily by many people for years, simply as a result of reading a paragraph like the above. The most they accomplish is to make their food taste horribly dull. If you need to reduce salt intake you should be in your doctor's care, and so please let him decide.

Congenital Heart Disease. It has been estimated that of all the babies born who survive at least one month, there will be about one in every two hundred with some form of congenital heart disease; that is to say that the heart will have failed to develop properly in embryonic life. In some cases this is associated with a virus disease of the mother (commonly rubella, or German measles) or with certain drugs taken by the mother (e.g. thalidomide) at a time, very early in pregnancy, when organs are assuming their adult shape. Parents should see to it that their daughters get German measles before they grow up; and drugs of all kinds should be avoided where possible during early pregnancy. In most cases of congenital heart disease, however, there is no known cause, and it seems that the manner of formation of the embryonic heart is so delicate that it can be thrown out of gear very easily, perhaps even by chance. Scores of different types of defect occur, singly and in combination. Any of the valves may be anatomically defective—either failing to close properly (*incompetence*) or being too tight (*stenosis*); the great vessels (pulmonary artery and aorta) may be switched round, or *transposed*, so that they emerge from the wrong ventricle; there may be defects in the wall (*septum*) which separates the atria or the ventricles on each side (*septal defect*, or " hole in the heart "); or there may be a persistence of the vessel which in the fœtus normally by-passes the lungs by joining the pulmonary artery to the aorta (*patent ductus arteriosus*). This vessel normally closes at the time of birth when the first breaths are taken, and subsequently disappears, so that the whole output of the heart is then sent round the lungs. Detecting congenital heart disease early is one of the purposes of routine post-natal check-up examinations of the baby. Exact diagnosis requires very complicated techniques, and sometimes the structural defect can be corrected by surgery, with almost miraculous results.

Rheumatic Heart Disease. Acute rheumatic fever is not to be confused with other forms of rheumatism. Many tissues of the body (particularly the heart) are attacked, as well as the joints, and the trouble is due to a sensitivity which has developed to certain bacteria (*hæmolytic streptococci*) which have probably caused a sore throat about three weeks before the onset of the disease. Why acute rheumatism only rarely follows streptococcal sore throat is poorly understood, but this is no consolation to the one per cent or so of the population whose hearts bear its scars. During the acute phase of the illness which usually occurs before the age of fifteen, inflammatory damage occurs to the valves, the heart muscle, and the sac in which the heart lives, the *pericardium*. So there is a *valvulitis* or *endocarditis*, a *myocarditis* and a *pericarditis*. There may be acute heart failure at this stage if the heart is severely affected. The better-known results of rheumatic heart disease, however, are caused in the ensuing years by scarring of the healed valves. The valves are thickened and deformed. They may have lost their elasticity and stretch, so that they do not close properly (*incompetence*); or they may contract and tighten (*stenosis*). In both cases the heart chamber situated next to the affected valve has to work progressively harder, either because it gets no rest in between beats (in *incompetence*); or it has to force the blood through too narrow a hole (in *stenosis*). The end result is some variety of heart failure (P27). Although there are other causes of valvular heart disease which will now be mentioned, rheumatic fever is much the commonest, and much valve trouble can be blamed on rheumatic fever even when the patient has no recollection of ever having suffered from it. The other, much rarer, causes may be syphilis, congenital valvular anomaly, healed bacterial endocarditis, atherosclerosis, and mechanical injury.

The most commonly affected valve is the mitral, usually causing *mitral stenosis*, in which the opening between the left atrium and left ventricle will sometimes only admit one finger-tip instead of three fingers as it should. In time the left atrium becomes much enlarged as it overworks to force blood through this narrow orifice. Later still a back pressure develops in the lungs causing congestion and breathlessness; and even later the right ventricle is strained as it tries to force blood into the already congested lung. This is a classic example of the march of trouble backwards from the site of the damaged valve involving first the chamber " behind " it (the left atrium), then the territory " behind " that (the lungs), then the pulmonary arteries taking blood to the lungs, and finally the right ventricle trying to send blood to the pulmonary artery. This steady march of events is usually very slow, and can commonly take twenty years or longer from the initial attack of acute rheumatism to the severer symptoms of advanced mitral stenosis. Treatment is both medical and surgical. The heart failure is treated medically as already described. These days surgical reopening of the valve is almost commonplace, either by inserting a finger through the left auricle and breaking down the constriction, or by opening up the heart and re-shaping the valve under direct vision. The latter involves the additional problem of by-passing the heart by the use of some sort of external pump and poses additional problems, even though from other points of view it is obviously more convenient. As always with major surgical procedures much of the problem is in selecting the patients who will benefit from the operation and in whom it is feasible. Quite often there are other valves involved, mainly the aortic or tricuspid or both, and the hydrostatic or " plumbing " problems can be extremely complex. With luck, however, combined with good judgement and good surgery, the lives of incapacitated patients can be transformed by mitral, and other valvular, surgery. Recently a great deal of progress has been made in designing new " ball-in-basket " valves of man-made materials to replace damaged natural valves. The *aortic valve* is stenosed or narrowed by other degenerative processes besides rheumatism. *Tricuspid stenosis* is nearly always rheumatic in origin.

Coronary Heart Disease. This is the term used whenever the blood supply to the heart muscle (through the coronary arteries) is reduced to such an extent that the heart muscle suffers from a lack of supplies. It has a number of causes, but the only really common one is partial obstruction of the coronary arteries by a condition known as *atheroma* or *atherosclerosis*, and sometimes inaccurately called *arteriosclerosis*. This arterial disease is described later (P30). It takes the form of swellings or lumps on the lining of the artery which, if they become large enough to interfere seriously with the flow of blood, produce a blood starvation or *ischæmia* of the tissue being supplied. Obviously, the smaller the artery, the more easily will a lump of given size impede the flow. Equally obviously, the greater the demand for blood, as in exercise, the more blood " starvation " there will be. There are two degrees of coronary artery disease: one in which the blood flow is reduced to the point where the increased demands of hard work cannot be met, and this results in *angina pectoris* due to *coronary insufficiency*; the other is when the coronary artery becomes completely blocked, preventing the flow of blood altogether, usually by a *thrombus* or clot of blood, and this is *coronary thrombosis*.

Angina Pectoris. Whenever activity is increased in any muscle, the demands for oxygen and nutriments from the blood-stream increase, and as these are used up there is an increased production of waste products known as metabolites. To meet these demands for a greater supply and a more efficient waste-disposal, the blood flow through the exercising muscle must always be increased. If sufficient increase does not occur, not only will there be a shortage of supplies, but there will also be a pile-up of metabolites in the muscle which cannot be carried away. It is mainly because of these latter that pain is caused in ischæmic, or blood-starved muscle, and pain is one of the chief symptoms when heart muscle becomes ischæmic. One important mechanism for increasing blood flow normally to exercising muscle is by automatically dilating the vessels concerned. Diseased vessels, such as

coronary arteries when they are affected by atheroma, are not so easily dilated, although certain drugs which are powerful dilators of arterioles can accomplish a great deal, albeit temporarily. The measures taken to relieve the pain and blood-starvation of angina are two-fold. The patient can reduce the demands of the heart by a few minutes' rest, and a drug (usually nitroglycerin) can be taken to dilate the coronary vessels of supply. Another obvious long-term way to reduce demands is for the overweight patient to eat less, and reduce the load of extra body weight on his circulation. It is very frustrating, to say the least, that such an incapacitating and often lethal condition should be caused by the narrowing or blockage of only two or three inches of narrow piping about one-eighth of an inch wide. One obvious form of treatment in theory would be surgical replacement of the piping (many larger arteries than these in other parts of the body are commonly replaced already); or surgical removal of the obstruction inside it. It is very likely that surgeons will one day overcome the technical difficulties involved.

Heart Attack or *Coronary Thrombosis.* It should readily be understood from the above description that heart attacks will vary in their severity according to the amount of heart muscle deprived of blood; and this in turn will depend on where in the coronary artery the obstruction occurs. Most usually it is the left ventricular muscle which is cut off from supplies and dies, either in part or in all of its thickness. Since it is the left ventricle which does most of the work of pumping blood to the body, serious heart failure (P27) is to be expected. If too much muscle is killed, the heart will simply stop, and the patient will suddenly die. It is much more usual, however, for enough muscle to be left for survival, albeit with a greatly reduced cardiac efficiency. A heart attack is usually accompanied by severe pain, similar to the pain of angina but more severe, and unrelieved by rest or by the patient's usual drugs. Very occasionally the event occurs apparently without pain, or with so little that it is ignored. These so-called "silent" coronary attacks can make diagnosis extremely difficult. Since the doctor depends very considerably with heart attacks on an exact, spontaneous description of symptoms for his diagnosis, no description will be given here. There are many over-anxious people who will read these words and could be misled into an unspontaneous description of their own symptoms, and this could make the task of treating them such a problem that they could even be mis-diagnosed as a result. If you have the smallest worry that your chest pain is due to your heart, take your anxiety to your doctor without delay. He will almost certainly be able to reassure you; and if it happens to be your heart after all, you will have taken the first sensible step towards proper treatment. Dangerous as heart attacks are, they are by no means the death warrant that many lay people think, any more than cancer is. The treatment for a true heart attack is urgent and prolonged. Patients must be at complete rest and their pain relieved quickly. The area of heart muscle they have lost must be allowed to heal with a good, firm scar, and this can take three months of rest often in hospital.

You can help to avoid a heart attack by not smoking, avoiding obesity and living a physically active life. Avoid sudden exercise, however, when you are not in training. Surgeons are getting better at replacing diseased coronary arteries with pieces of vein from elsewhere.

Blood-pressure. The blood is normally under great pressure in the arterial system, since it is this which forces it into all the tissues of the body. It is therefore no more meaningful to say you have "blood-pressure" than to say you have a temperature. You would be very badly off without. Blood-pressure which is too high, however, can give rise to problems, though not always. It is another of those conditions like angina and cancer, which engender much anxiety among people even when they do not suffer from them. For this reason doctors are often unwilling to disclose a patient's blood-pressure and because of this they unjustifiably earn a reputation for unreasonable secrecy. They are themselves to blame for the general public anxiety as the following true story shows. Twenty years ago a lady in her fifties wished to accompany her husband to a post abroad which was to last four years. All arrangements had been made—the husband resigned his previous job, sold the house, etc.—when it was discovered at a routine medical examination that she had a high blood-pressure, and she was very solemnly advised by the rather elderly doctor not to go. There was great consternation and emotional upheaval, not least because of the inconvenience involved. Eventually she was allowed to go at her own risk. The husband's job lasted eight years instead of four, during which the lady was in no way inconvenienced by her blood-pressure; except that she worried interminably about it. On returning home to retire she began to think she had angina, and elaborate hospital investigation revealed that, as might be expected, her arteries were not as young as they used to be. She was undoubtedly suffering from mild angina, but not as badly as she thought. The opportunity then arose, in her late sixties, to go abroad yet again, and this she did, living a quite strenuous life, and one which she enjoyed. At the time of writing she has returned home, and, twenty years later, at the age of seventy-three is running a home very actively, still with very little inconvenience from her blood-pressure. There is no doubt that it has been very high all this time, and it is also certain that she will die one day, although it may well not be of her blood-pressure. How much better it would have been for her not to have been told it was high twenty years ago and to have avoided all these years of anxiety. It is not being suggested here that high blood-pressure is a trivial condition, but that it is for doctors to worry about rather than patients! If you ever find out your own blood-pressure, never try to work out for yourself what the figures mean. It is much too complicated. Finally, it should be mentioned that high blood-pressure may occasionally be associated with, or "secondary to," certain kidney diseases (*nephritis*) including a strange condition known as *toxaemia of pregnancy*, which lasts only as long as the pregnancy, provided great care is taken. Most high blood-pressure is, however, "primary", and without any known association or cause.

Low Blood-pressure. Some people seem normally to have surprisingly low blood-pressure all the time. There is nothing whatever wrong with this; indeed it may even be beneficial. At least they are unlikely ever to suffer the effects of high blood-pressure. The sudden low blood-pressure of circulatory failure or shock (P27) is another matter and must be urgently treated.

Irregularities of the Heart-beat. How quickly or how slowly the heart beats is largely under the control of the cardiac centre in the brain and the level of certain hormones in the blood. The *regularity* of the beat, however, is controlled by the so-called pace-maker in the wall of the right atrium, and by the way impulses from the pace-maker travel through specialised conducting heart cells (the bundle of His and its branches) to the ventricles. When any part of this elaborate mechanism is upset, either by altering the biochemical or electrical conditions of these specialised tissues, or by killing some of them off by deprivation of blood supply in the course of a heart attack, disordered rhythm can result. Increase (*tachycardia*) or decrease (*bradycardia*) in rate is nearly always a normal response to exercise, or anxiety. Very occasional irregularity, such as the mis-timing of an occasional beat is also quite normal in some people, although many are alarmed by it. Persistent irregularity, however, is abnormal. Its true nature can usually be elucidated by making an electrical record of the heart-beat—an electro-cardiogram. The commonest causes are varieties of coronary artery diseases or rheumatic heart disease.

Pericarditis. The heart beats inside a bag or sac. At every beat its outer surface slides against the lining of the sac, lubricated by a small amount of fluid. This is the pericardial sac, the

pericardium being strictly the lubricated membrane which lines the sac and which also covers the outer surface of the heart. Sometimes inflammation occurs—*pericarditis*—and the sliding surfaces become roughened and even separated by a fluid effusion. Very occasionally, so much fluid accumulates that the heart's action is seriously impeded. Pericarditis may be due to infection or to rheumatic fever, and it usually overlies the area of damaged muscle after a heart attack. This illustrates something which people rarely appreciate—that inflammation is not by any means always due to infection by bacteria. The last two varieties of pericarditis are quite free from germs (sterile).

Myocarditis. A term loosely applied to disorders affecting the heart muscle. There are lots of very rare causes. The really common ones are due to acute or chronic rheumatic causes or to coronary artery disease, both of which are described above.

Endocarditis or inflammation of the lining of the heart is a term loosely applied to any disorder of the valves or heart lining. All varieties of rheumatic valvular disease (P28) are included. Bacterial endocarditis in its several forms usually involves valves already damaged by rheumatic disease. It is a complication which is still much to be feared, though somewhat less so now that antibiotic drugs are available.

Atheroma or Atherosclerosis. This is the condition referred to above in which lumps arise on the lining of arterial blood-vessels. Although it is therefore a disease of the arteries, its importance lies in the way blood flow is held up, either by the lumps themselves, or by thrombosis ultimately blocking the narrowed portion of the pipework. The effects on the body are therefore those of depriving the tissues of blood. It is an astonishing fact that in England and America, more people die of the consequences of atheroma than of any other single disease, including all forms of cancer put together. Furthermore, cancer is mainly a disease of old age, whereas many of the effects of atheroma on men occur in early middle age. If narrowing of the artery is going to do significant harm it is easy to see that it will be of more consequence in those parts of the body where small-bore vessels are supplying tissues whose functions are necessary for life. Exactly such a situation exists in the heart and in the brain. An additional factor is that the arrangement of the blood supply in these tissues is such that any particular area has only one vessel leading to it. This is unusual among the tissues generally, where several alternative, or "collateral" vessels usually supply an area, and where others can take over if one becomes obstructed. We have, therefore, a situation in which perhaps the most important tissues —the heart and the brain—run the greatest risk of deprivation, and this leads to angina and coronary thrombosis on the one hand, and cerebral thrombosis and hæmorrhage ("stroke illness") on the other, accounting jointly for about one death in every five. In addition, the effects of atheromatous narrowing are often felt in the legs, where the blood supply to the muscles is inadequate for exercise, leading to intermittent pain comparable with that in the heart in similar circumstances. This is called *intermittent claudication*, or intermittent closing of the leg arteries. In its most severe forms, it leads to the need for amputation, although in most cases early treatment can avoid this. It is small wonder that there is intensive research into the causes of atheroma, as with cancer, but it is probably true to say that we still know rather more about cancer. A lot of attention has been given to the amounts of certain fats in the circulating blood, particularly cholesterol. This fat is found in larger amounts in the blood of sufferers from atheroma, and is also found in the arterial lumps themselves. Efforts have therefore been made to reduce blood cholesterol by modifications of the diet, but it has been extremely difficult to prove that this has done any good. Many other factors are known to contribute to atheroma, and hence to heart attacks and strokes, some of which can be reduced and others not. Such factors are age, obesity, high blood-pressure, and smoking cigarettes. People who lead an active life, like bus conductors, seem to have less trouble than others who are less active, like bus drivers. Sudden severe exercise, however, is bad if you are not used to it. It is better, and life saving, to take regular, moderate exercise. Women have less atheroma than men, until the menopause when they begin to catch up, so that hormones have something to do with it. Serious starvation, such as occurred in the German-occupied territories of Holland and Scandinavia and in the concentration camps conferred one benefit—a freedom from atheroma, but obviously we cannot all starve, and the puzzle remains. Like many of the more important outstanding medical puzzles, there is no single factor responsible, and this is what makes it difficult to solve.

Aortic Disease. The aorta, the main artery of the body, running from the left ventricle down through the chest and abdomen, also suffers from atheroma, but is too wide (about an inch across) to become obstructed. However, weaknesses occur in the thickness of its wall, sometimes due to syphilis but nowadays much more usually due to atheroma, which results in a ballooning out of a part of the vessel, rather like you sometimes see in an old bicycle inner tube. In days gone by these *aneurysms*, as the dilations are called, reached an enormous size, and would wear away the breastbone and ribs, to appear as large pulsating masses on the chest. Now that advanced syphilis is less common, atheromatous aneurysm, with a predilection for the abdominal aorta, is the one most commonly seen; and these days it is treated by replacement of the diseased portion of vessel. *Dissecting aneurysms* of the aorta are another variety in which the blood, under high pressure, somehow finds its way in between the layers of the aortic wall and then suddenly rips up and down the whole length of the vessel, separating (or dissecting) one layer from another in its path. Sometimes it tracks back towards the heart and suddenly fills the pericardium with blood to stop the heart's action altogether.

Embolism. This term refers to any foreign object travelling in the circulation and becoming impacted when it reaches a vessel too small for it to pass through. It may be a thrombus (P31), a collection of cancer cells, a group of bacteria, a chunk of infected pus from an abscess, a collection of fat droplets or even a bubble of air. If it originates in a vein it travels to the right heart and to the lungs. If it comes from the left heart or an artery, it will impact in any part of the arterial tree. Reasonably enough an arterial embolus will commonly end up in those parts of the body with the richest blood supply, like the brain, the kidneys, the liver or the bone marrow. A thrombotic embolus will cause death of the tissue in the area previously supplied by the blocked vessel, a condition known as *infarction*. Perhaps the commonest source of thrombotic embolism is the lining of the heart chambers where a thrombus has occurred at the site of muscle damaged by a heart attack. Massive pulmonary (lung) embolism is usually the result of thrombosis of the leg veins in people kept immobile following surgery or childbirth. That is why postoperative patients are got out of bed for a while as soon as the first day after the operation. The cells of a cancer embolus usually die; but if they survive, a new cancer deposit begins to grow where the embolus impacts, and this is one of the ways cancer may spread. An infected embolus may infect the vessel wall when it impacts, producing a weakness which may give way. Air embolism, if enough insoluble gas enters the circulation, can kill by making so much froth in the heart chambers as to impede the normal pumping action. If bubbles pass the lungs and enter the brain, all sorts of neurological disorders like scores of tiny strokes arise. The same sort of thing happens all over the body in the "*bends*" or "*caisson*" *disease*, in which the blood literally boils. It is due to a too rapid return to normal pressure from regions of high pressure at great depths or from pressurised chambers. Fat embolism sometimes occurs after

fractures due to marrow fat entering damaged veins and being carried away to the lungs.

Thrombosis. This is not quite the same as clotting. It is the mass which arises when platelets adhere to the lining of blood-vessels or heart chambers. Blood clot accumulates among layers of deposited platelets and the thrombus therefore has structure, unlike pure blood clot. Thrombosis usually occurs when the lining of the vessel or chamber is damaged by atheroma or inflammation, or when the circulation becomes very stagnant. One danger is that it will become dislodged and travel as an embolus during the first week or ten days of its existence. After this time it is usually firmly incorporated into the vessel walls by cells which migrate into it from the surrounding tissue. The other danger is, of course, that the tissue previously supplied by the blocked vessel will die before a collateral circulation can be established. As previously explained, this is called infarction. All the technical terms in this section are used elsewhere and can be looked up.

Varicose Veins. When veins become swollen they also often become tortuous (wriggly), and particularly on the surface of the leg look very unsightly. They are, however, a sign of a sluggish circulation, and are often due to disease in small valves within the veins which normally prevent the blood from pooling backwards, down towards the feet. They are often a normal maternal accompaniment of pregnancy and disappear after the child is born. If allowed to persist, the sluggish circulation allows the formation of unpleasant ulcers, mainly in elderly people. Treatment is according to severity. In the early stages they are helped by supportive stockings. Later, often as an out-patient, the sufferer may have to have them removed or obliterated by a surgeon.

Reynaud's Disease. This is a strange condition in which the finger tips and in severe cases all the fingers or the whole hand respond in an exaggerated way to cold. The vessels supplying the hand are constricted and the fingers go white as the blood drains from them. Then the capillaries dilate and become distended and filled with blood. But owing to stagnation it is venous and blue, and the fingers are therefore blue. Now we have all experienced this in very cold weather, but sufferers from Reynaud's disease, nearly always women, respond even to very slight cold, like putting their hands into cold water. Even emotional stress will start the process off. In very severe cases the fingers will be so deprived of blood for so long, that sores will develop and fingers can even be lost, but this is very rare, and can be avoided by an operation to cut the nerves which supply the circular muscle of the vessels concerned. In most cases it is sufficient to avoid getting the hands cold.

Frostbite. Strictly speaking, this is literally a freezing of the tissues. Although their freezing point might be expected to be close to that of water, it usually only occurs at temperatures below −13° C (8° F). The patient may feel a pricking feeling at first, and feel an area of firmer, pale skin on the cheeks, nose, ears, fingers, or toes. If these parts are numb with cold, the onset of frostbite may not be felt, and will often only be noticed by others. In countries where extreme cold is prevalent, it is usual for complete strangers to stop each other in the street and point it out when they see it. It is important not to rub the affected part, but contrary to popular belief it must be warmed as *rapidly* as possible. Fingers should be immersed in water as hot as the normal hand can bear (110° F). Many First Aid books still quite wrongly teach that return to warmth must be gradual.

DISEASES OF THE RESPIRATORY SYSTEM.

INTRODUCTION.

When air is drawn in during the process of breathing, it is brought into very close contact with the blood passing through the lungs. In this way the air we breathe in, which contains 20 per cent oxygen, is confronted with "spent" blood returning from the tissues which contains much less, and oxygen therefore diffuses into the blood from the air. At the same time, the waste gas, carbon dioxide, passes by diffusion in the reverse direction from the blood into the air, because there is much more carbon dioxide in the returning "spent" blood than the tiny amount in the air we breathe. The blood is therefore continually circulating through the lungs and exchanging carbon dioxide for oxygen from the air we breathe in. When we breathe out, we disperse the carbon dioxide into the atmosphere.

When the air enters the nose or mouth, it passes into the windpipe or *trachea*, through the vocal cords in the pharynx. The trachea is held open all the time by rings of cartillage and is lined by a mucus-secreting membrane covered by millions of tiny "hairs" or cilia. These continuously waft a sheet of sticky mucus upwards, which traps any dust or other small particles we may have inhaled, until a collection of this material in the pharynx stimulates us to cough and expel the phlegm, usually to be swallowed. At its lower end, the trachea or windpipe divides into two, the right and left main *bronchus*. Each main bronchial tube enters a lung, one on each side, and proceeds to divide repeatedly within the lung until the air is being carried by more and more smaller and ever smaller tubes called *bronchioles*. There are many millions of these on each side, and each one ends in a collection of very small balloon-like structures —the air sacs or *alveoli*. If you were to cut across a lung and examine the cut surface in a good light, you would see that it is a spongy tissue, with many millions of tiny holes, each one just visible to the naked eye. These are the air sacs. In their walls run the blood capillaries, each one of which is a branch of the vessels carrying "spent" blood from the right side of the heart. At this stage, the blood is only separated from the air in the sacs by the walls of the capillaries and of the air sacs themselves. Both structures are extremely thin, making for easy diffusion of the gases between blood and air.

The action of breathing is accomplished by two muscular mechanisms. One is by the muscles which move the ribs, and the other by the diaphragm, a sheet of muscle which runs across the body, separating the chest cavity from the abdominal cavity. These muscles are all actuated by nerves, just as all other muscles are. Those running to the muscles of breathing are organised by a mechanism in the brain known as the *respiratory centre*. It is this centre—one of the so-called vital centres of the brain—which receives information from many different sources, and translates it into instructions for the breathing mechanism. Thus, when you run for a bus, you will automatically breathe more deeply and more quickly because the respiratory centre has been informed about all the extra carbon dioxide in your blood which has been produced by the exercising leg muscles. Even the conscious instructions involved when you blow a trumpet, inflate a balloon, or during speaking, all pass first to the respiratory centre. It is the death of the cells of this and other vital centres of the brain that is the ultimate cause of death in everyone who dies.

Bronchitis may be acute or chronic. It is an inflammation of the lining mucous membrane of the larger air passages or bronchi, and results in much more secretion than the amount normally produced, mixed with some pus. The acute form is often caused by viruses, with "secondary" infection from bacteria. It may sometimes be caused by irritant gases, like the sulphur dioxide in smog. The chronic, or long-standing form of bronchitis is often associated with *emphysema*, in which the small air sacs of the lung architecture are destroyed or distorted, leaving larger spaces than normal, often surrounded by fibrous scar tissue. Such an arrangement makes the normal gaseous exchange difficult between air and blood. While the exact cause of chronic bronchitis is difficult to discover, because it is such a mixture of causes, it is mainly associated with older age groups, particularly men, in damp foggy climates

like ours in Britain, with polluted town air and especially with smoking. Smoking also makes any existing bronchitis much worse. Bronchitis can cause even more trouble than lung cancer, since instead of dying in a short time, the bronchitic lives for many years in chronic sickness. About 30,000 people die of bronchitis each year. It isn't smart to smoke. Patients cough, and produce varying amounts of sputum, or phlegm. They often wheeze like asthmatics. This may go on for many years before the right side of the heart begins to fail (P27). Gradually, during this time, the chest tends to become barrel-shaped. Treatment consists of getting the patient to stop smoking or otherwise contaminating his lungs, preventing infection, particularly during winter months, with germ-killing antibiotics, and breathing exercises. The outlook for chronic bronchitis and emphysema is nevertheless not good, although many patients contine with their disease for many years, provided they take constant care to obey instructions and stop smoking.

Bronchial Asthma (not to be confused with *cardiac asthma*) is a condition in which the finer air passages become constricted due to an allergic response. In addition, an increased secretion tends to obstruct them and the patient wheezes. In many cases it can be shown that he is allergic to a particular component of dust, or, less commonly, a foodstuff. This is the same sort of thing as occurs in the upper respiratory passages in hay fever, but the effect is on a different, lower part of the respiratory system. Many other cases are due to respiratory infection of some sort, probably combined with an allergy to the bacteria causing it. A predisposition to asthma is often inherited. Once a patient has become asthmatic, his attacks will be triggered off by such additional things as emotional stress, changes in temperature (particularly sudden cold), irritating fumes or smoke, and physical exertion. These are secondary factors, and although much of the treatment is concerned with them, it is unlikely that any of them are a sole cause of the condition. Treatment is directed at the relief of the breathing difficulty and of the wheezing, as well as the control of the causative factors. Many useful drugs are available to dilate the contracted air passages and reduce the obstructing secretions. Asthma in children often gets better as the patient grows up. Asthma is another condition made much worse by smoking. Patients should avoid extremes of cold and humidity, particularly outdoor exertion in cold, damp weather. They should also avoid exposure to respiratory infection.

A tiny living mite about 0·3 millimetres long exists in large numbers in nearly all mattress and floor dust. This is the cause of much asthma, and in such cases it is often very helpful to vacuum-clean mattresses and floors frequently.

Bronchiectasis. In this condition the bronchial air passages are abnormally and permanently dilated, and the normal structure of the walls destroyed. It is thought to be caused by obstructions of the tubes which lead to dilatation of the parts beyond. Secretions accumulate, and since they cannot easily drain away, they become infected. The infection helps to complete the process of destruction of structures in the bronchial wall. The patient has a chronic cough which often produces large quantities of purulent sputum, and there are often recurrent episodes of pneumonia. Diagnosis is made by a special X-ray examination—a bronchogram—in which a material, opaque to X-rays, is dropped into the air passages. This shows up the dilated and distorted tubes. In some cases, where the disease is localised to one part of the lung, it is often a good idea to cut out that portion, and this is particularly true in young people. Vigorous physiotheraphy, involving drainage of the lungs by placing the patient in a suitable posture, together with antibiotic drugs for the infection, are other forms of treatment.

Cystic Fibrosis is an inborn disease which affects chiefly the lungs and the digestive system. It is sometimes called *Fibrocystic disease of the Pancreas*, and sometimes "Mucoviscidosis" Until it was medically recognised twenty-five years ago, children affected usually died from pneumonia in the first year of life. This, of course, was before antibiotics were available for the treatment of infections. Today, cystic fibrosis is known to be the commonest genetically determined disorder affecting children in Britain. One child in 2,000 receives one of the abnormal genes from each parent. Such a child therefore has a double dose of the harmful gene, and will have the disease from birth. One person in 25 of the general population carries only one of these abnormal genes, and such an individual will not have the disease, but will be a carrier of the abnormal gene. If such a seemingly normal carrier marries another carrier, there is a one in four chance of each of their children being affected. The children, therefore, who actually develop cystic fibrosis, have inherited the disease *equally* from both parents, who are carriers, but are themselves unaffected by the disease. Although much has been learned about cystic fibrosis in the past twenty-five years, there remain many unsolved problems, and we still cannot define precisely the biochemical fault which causes it. The prospects for survival into reasonably healthy adult life are steadily improving, but they depend upon early diagnosis and careful management through childhood. In cystic fibrosis most of the damage is caused by the excessive viscidity, or stickiness, of the mucus which is produced in the breathing tubes as a lubricant, and also in the ducts of the pancreatic gland which provides enzymes to help digestion. Being thick and sticky, instead of thin and slimy as in the normal, this mucus tends to block the passages instead of keeping them clear. The pancreatic cells are permanently destroyed. The gland cannot secrete pancreatic enzymes, and the food, especially protein and fat, is not properly absorbed. This deficiency can be compensated fairly well by giving pancreatic extract by mouth with every meal, and by dietary care.

The major clinical problem is in the lungs. The lung passages normally have a thin coating of mucus which is propelled steadily upwards, and is completely renewed in less than one hour. It moves more suddenly on coughing. In cystic fibrosis this upward movement is slowed down and interrupted. There is difficulty in keeping the passages clear, especially when infection with bacteria or viruses greatly increases the amount of mucus. This results in intermittent blocking of the air passages, difficulty in breathing, incomplete use of the lungs, and persistent local pockets of infection. If such infectious processes are not controlled, areas of lung will be destroyed, chronic infection will persist, and multiple lung cavities will develop. These predispose to further infection, interfering with the natural development of the lung—a process not normally complete until halfway through childhood—thus adding to the respiratory problems which the child will face in later life. Unless a correct diagnosis is made, and proper treatment instituted before the first serious lung infection has occurred, the resulting lung damage may well be permanent.

Pneumonia. This is an infection of the lung tissue, rather than of the air passages. The lung is the only internal organ which is directly exposed to the air, and since there are germs of all kinds in the air, it is a source of surprise that pneumonia is not a much more common event in all of us. The answer lies, as with all infections, in the fact that it is not simply (or even mainly) bacteria which cause disease, but our own lack of resistance to them. If we allow germs to thrive and multiply by being unhealthy or run down or undernourished, infective disease will occur. If we are fit, the entry of those same harmful germs into the body causes us no inconvenience, unless we are very young, or very old, or unless the invasion of germs is abnormally overwhelming. This helps to explain why pneumonia is so often quoted as a cause of death. In most cases it is merely a terminal event occurring in the elderly sick, whose normal resistance is so far reduced by their illness that they succumb to an invasion which they would normally not notice. There are two main kinds of pneumonia, and in both the air sacs

become filled with inflammatory secretions, making the normally porous lung tissue as solid as liver. In *lobar pneumonia*, a whole segment (or lobe) of the lung becomes solid. In *bronchopneumonia*, areas of lung tissue surrounding the smaller bronchioles become consolidated, leaving normal porous lung tissue in between. Bronchopneumonia is the one which occurs in the rather stagnant lungs of people who are already ill or bedridden. Both forms respond to treatment with the appropriate antibiotics, provided any underlying debility does not interfere with the patient's own resistance. In the terminal bronchopneumonia of fatal illness, it is sometimes considered kinder not to treat the additional pneumonia. *Pleurisy* is a natural complication, and before the days of antibiotic drugs *lung abscess* was very much feared. Another form of pneumonia—*virus pneumonia*—is referred to on P10(2).

Pneumoconiosis. This is a term which refers to a large group of different diseases, all of which are caused by breathing in some form of dust over a very long period of time. It is therefore an occupational hazard of certain trades. We have already mentioned the mechanisms of mucus secretion in the air passages which normally trap small particles from the air, and prevent them reaching the lung. However, in some occupations there is so much dust breathed in over the months and years that these normal barriers are defeated. About a quarter of the earth's crust consists of silicon, in quartz, flint, or sand. *Silicosis* occurs in people who have worked for many years in trades like mining, stone crushing, sandblasting, or metal grinding, who are often breathing silicon dust in high concentration. When the particles arrive in the air sacs, they set up an irritant chemical reaction which produces nodules of scar tissue. Silicosis for some reason predisposes to tuberculosis (P14(1). Emphysema also occurs and there is a general impairment of respiratory function. Coalminer's pneumoconiosis is similar to silicosis but not identical with it. It is more prevalent in some coalfields than others, owing to the different composition of the dust to which these unfortunate men are daily exposed. It is hoped that modern mining methods will help to reduce this dread disease. Asbestos is a complex silicate of magnesium, calcium, and iron. *Asbestosis* is caused by inhaling its fine fibres. *Berylliosis* is caused by compounds of beryllium, used in the manufacture of fluorescent lamps. *Farmers lung* is a pneumoconiosis caused by inhaling hay and grain dust, and is similar to *bagassosis* and *byssinosis* caused by sugar cane and cotton dust respectively. The newest pneumoconiosis to be reported is *mushroom worker's lung*, caused by something in the compost in which mushrooms are commercially grown.

Pulmonary Embolism. This catastrophic, yet quite common condition has already been briefly referred to (P30(2)). It is a cause of tragic, sudden death in people who have had operations or have given birth to babies some days previously, or who have been bedridden for any other cause. The first event is that the blood in the veins of the legs becomes stagnant, due to the lack of exercise; and together with the tendency to clot which often follows surgery or childbirth, the whole length of a leg vein may be obstructed for twelve inches or more by an elongated clot of blood. This does little harm to the circulation of the leg, since there are plenty of other veins for returning blood to the heart. The danger is that the clot will become dislodged and be swept upwards towards the heart by the flow of returning blood. When this happens it is carried by way of the right auricle and ventricle into the pulmonary vessels which normally carry spent blood to the lungs. Here, for the first time, it enters vessels which are getting smaller as they divide, and it then impacts in the main pulmonary artery. The patient, who may have been recovering very well, suddenly collapses and not unusually dies there and then. At autopsy a long coiled-up mass of clot is found obstructing the pulmonary vessels. It often can be seen to form a cast of the leg vein and even bears the marks of the small venous valves which are present at its site of origin. With the dramatic advances being made in chest surgery, it is now sometimes possible in selected cases to operate to remove the clot. Success clearly depends on the patient's surviving long enough to be taken to the operating theatre for the major operation of *pulmonary embolectomy*. Three quarters of all cases of pulmonary embolism die within two hours, and therefore the best hope would be to prevent the occurrence altogether. This is not at present possible, but clotting in leg veins can be discouraged by early exercise following surgery and childbirth. Patients often resent having to get up the next day because it is so uncomfortable. Herein, however, lies their best hope of avoiding pulmonary embolism.

Hæmoptysis. This means coughing up blood or blood-stained material. It must be distinguished from *hæmatemesis*, in which the blood is vomited from the stomach. It must always be taken seriously because of the underlying lung disease which may be present. No one who coughs up blood, in however small a quantity, should neglect to inform their doctor so that its source can be determined. Hæmoptysis occurs in a variety of lung disease, some of which is not serious but much of which must be treated immediately if it is not to become so. This is a suitable place to repeat our general rule that you should see your doctor without delay if you have any unexplained bleeding from any part of the body, however well you feel. And this includes hæmoptysis.

Fat Embolism. Liquid fat sometimes enters the bloodstream following extensive crush injuries to soft tissue and bone. It splits up into millions of small globules which are carried to the lungs, and impact in small blood vessels there, producing obstruction of the lung circulation and consequent difficulties in breathing.

Lung Cancer. This is one of the commonest, nastiest and most incurable forms of cancer which can occur. It is also probably the easiest to prevent. In 1969, 29,768 people died of lung cancer in Great Britain, all but 5,000 of them men. Every year the toll goes up. There has been no reasonable doubt for several years now that it is associated with cigarette smoking, and the evidence is overwhelming. However, in spite of this certain knowledge, smoking continues to increase, and every year there are more and more people dying unpleasantly of lung cancer. It seems that nothing the health authorities can do is able to stop it. Intensive campaigns of public advertising of the dangers, and well organised instruction in schools have so far made no impression whatever on the smoking habits even of people who accept the evidence. The only group of people who are known to have stopped smoking are British doctors, very many of whom have given it up, and it is easy to show that giving it up has saved them from the disease. Their colleagues who have not done so have continued to die. Undoubtedly a large factor contributing to the failure of anti-smoking propaganda is the enormous expenditure by the tobacco manufacturers on very clever advertising, amounting to many millions of pounds each year. Moreover they spend a pitiful fraction of this amount on their own research into the harmful effects of their own product, which has so far discovered nothing which was not already known by research doctors many years ago. Another problem is that it takes a number of years to get cancer. It is not like an infectious disease which is caught a few days after exposure to the bacteria concerned. It may be fifteen or twenty years before the cancer begins, and many smokers are apparently unwilling to look so far ahead. Furthermore, not everyone who smokes dies this way; and so a smoker can gamble with his life and hope it will not be him. The present writer once had to perform a series of post-mortem examinations on people who died of lung cancer, and this helped him to stop smoking completely, having smoked more than twenty cigarettes a day for several years. Not everyone can have this incentive. The main

encouragement to smoke probably comes from other people. Schoolboys are easily impressed when their teachers and parents stop smoking. They are not likely to fear the habit when these same people smoke openly. The smoking doctor is also a powerful stimulus to people to carry on smoking.

Lung cancer grows in the wall of a main bronchial air passage. If it grows inwards it can obstruct the air way, choking that part of the lung it is supplying with air. This causes collapse and infection of the lung and may lead to *lung abscess*. The patient will then cough up blood-stained infected and purulent material. Such a case is comparatively lucky, since the disease declares itself early by producing symptoms. In others, the lump may grow outwards into the surrounding lung and produce no symptoms at all in the early stages. Indeed, it may spread to other parts of the body, like brain or bone or liver before causing any trouble to the patient. If this happens he may go to his doctor because of fits, changes of personality, or fracture, only to discover that the origin of the trouble is in the lung.

The chances of cure are negligible, although much can be done to relieve the pain and suffering of the last stages of the illness. Not more than one in twenty cases is alive two years after it is first diagnosed. Surgery, by removing the lung, and irradiation of the growth are the standard palliative treatment. It is not the practice of the Medical Section to alarm the reader unnecessarily, but if only a few are induced to stop giving themselves such a horrible disease, then writing in this way will have been justified.

Secondary Cancer of the Lung. In nearly all forms of cancer, the big problem is that it spreads to other parts of the body. If this were not so it could be eradicated by surgical removal more often than it is. One common way in which it spreads from any part of the body is by entering the bloodstream and being carried as clumps of living cancer cells to distant parts. When these come to rest in smaller blood vessels, they begin to grow and colonise the new environment. Such new colonies are called *secondary deposits* or *metastases*. It so happens that all veins (except portal veins of the liver) lead to the right heart and thence directly to the lungs, and for this reason the lungs are a very common site of *secondary* cancer, which may have begun in the bowel, or breast, or indeed anywhere else in the body. Other common sites of secondary, blood-borne cancer are the brain, liver, bone marrow, and kidney, since all of them have an abundant blood supply, and there is therefore a high chance of the travelling cells arriving there. Secondary cancer of the lung usually consists of several lumps scattered throughout the lung. Lung cancer itself is usually only one growth. One of the main reasons for the success of early diagnosis is that treatment may be possible before blood-borne and other means of spread have occurred. Unfortunately, in the case of primary cancer of the lung, even early diagnosis is of little avail, but in many other common cancers permanent cure is possible if treatment is begun early enough.

Pleurisy. The chest is lined by one layer of a thin membrane called the *pleura*. The lungs are covered and enclosed by a second, continuous layer of this same membrane. When the lungs move during respiration, the pleura covering the lungs rubs against the pleura lining the chest, lubricated by a very thin layer of pleural fluid separating the two pleura. Whenever the pleural surface becomes inflamed, this is known as *pleurisy*. It is nearly always due to inflammatory disease of the adjoining lung, and is therefore not strictly a disease in its own right. For example, pneumonia, tuberculosis, lung cancer, or a lung infarct (P30(2)) will produce a pleurisy if the area of diseased lung adjoins the lung surface. Sometimes the area of inflamed inner pleura will tend to stick to its outer layer or rub painfully against it, producing a sharp pain when the patient breathes. Sometimes a large effusion of fluid is produced which separates the two layers and collapses the lung by occupying space in the chest which the lung should be occupying. This latter is more usual in tuberculosis or cancer.

The lung can be collapsed by the entry of anything between the normally adjacent layers of pleura. For example, air can be introduced, either deliberately to rest the lung in tuberculosis, or by accidental penetrating wounds of the chest wall, or by accidental rupture of the emphysematous lung (*q.v.*). This condition is called *pneumothorax* or "air in the chest." Bleeding into the cavity between the pleura is called *haemothorax*.

DISEASES OF THE DIGESTIVE TRACT AND LARGE INTESTINE.

INTRODUCTION.

The digestive tract consists of the mouth, pharynx, œsophagus (or gullet), stomach, small intestine, large intestine (or colon), rectum, and anus. The small intestine is very long, and is subdivided into the duodenum, jejunum, and ileum. It ends at the junction of the ileum with the cæcum, where there is a small blind side-tube, the appendix. The cæcum leads into the colon. The whole tract has two main mechanical functions and two main biochemical ones. Mechanically, food has to be chewed in the mouth and further minced up by muscular squeezing, mainly by the stomach. It has also to be propelled along by an orderly series of squeezing movements known as *peristalsis*. While it is still in the digestive tract, food has to be digested. That is to say, it has to be broken down chemically into suitable materials for absorption into the system, and secondly, it has to be absorbed across the wall of the intestine into the blood stream, itself a highly complex biochemical process. The blood stream it now enters is a special part of the circulation, the "portal" system, which travels directly to the liver without first passing to the heart. In the liver the broken-down foods are processed and issued in their new form into the general, or "systemic" circulation, by which they are finally carried to all the tissues of the body.

As the food passes along the digestive tract (or, as it is sometimes called, the alimentary canal), it is mixed with various secretions which are either made in the wall of the tract, or by organs outside the wall connected to the main pathway by small tubes. Examples of the latter are bile, manufactured by the liver and sent into the duodenum through the bile ducts. Also pancreatic juice comes from the pancreas down the pancreatic ducts, also into the duodenum. These secretions are either digestive juices concerned with splitting up the foodstuffs so that they can be absorbed, or they have a lubricant function so that the gut contents slide along easily under the influence of peristalsis. Roughly speaking, it may be said that digestive juices give place to lubricant secretions at the junction between the small and large intestine.

The constituents of the diet are dealt with in a later section. The principle classes with whose digestion we are now concerned are carbohydrates, proteins, and fats.

Carbohydrates are sugars and starches. There are many sugars, which may exist alone, in pairs, or with lots of them stuck together. Alone they are such things as glucose or fructose. Common table sugar is a substance called sucrose, formed by sticking one glucose molecule to one fructose molecule. Starch is lots of glucose molecules all stuck together. Digestion of carbohydrates consists of splitting up sugars and starch into single sugars like glucose, since only single sugars can be absorbed into the system. The splitting is done by digestive *enzymes* which are found in the juices secreted into the digestive tract. Sugar-splitters are found in the saliva of the mouth, in the pancreatic juice of the duodenum, and in the duodenum's own juice from its own wall. On the face of it, you might think it would be better to eat glucose which needs no digestion and can be absorbed in

this form, than to eat starch which has first to be split; and so a lot of money has been made out of a gullible public by the sale of glucose drinks and powder. In fact digesting starch is no problem whatever, even for the sick, who can obtain their carbohydrate energy just as easily (and much more cheaply) from potatoes as from expensive glucose. The end result of eating both is the same. The starch-splitting enzyme in saliva is mixed with the food as it is chewed, and it is therefore probably a good idea to chew it well. However, even if the food is bolted it does not seem to matter very much. People without teeth (neither their own nor dentures) seem to digest their carbohydrate quite well, presumably by means of their pancreatic juice at a later stage.

Proteins, which are found in meat, cheese, and eggs, have very large molecules consisting of lots of small ones strung together. Unlike starch, in which all the component glucose molecules are identical, the amino acids of which proteins are composed come in many different types. They all contain nitrogen, and there are about twenty-seven varieties. One protein differs from another in the proportions of the mixture and the order in which they are stuck together. Only single amino acids can be absorbed from the food, and so protein digestion again consists of splitting the material down into its building bricks. There is a strong protein splitting enzyme in the gastric (or stomach) juice called pepsin, whose job it is to split the long amino-acid chains into shorter chains. Several other protein-splitters in the duodenal and pancreatic juice contrive to break the smaller chains into individual amino acids which are then absorbed and sent to the liver for processing.

Fats mainly consist of glycerol to which are attached three fatty acid molecules for each molecule of glycerol. An enzyme in pancreatic juice splits the fatty acids off the glycerol, but would have some difficulty penetrating the globules of fat without the help of bile. One of the constituents of bile (bile salts) has detergent properties like washing-up powder and breaks the fat globules up into a very fine suspension so that the enzyme can get at the fat. Some fat particles of this size can even be absorbed as such, without preliminary splitting.

The processes by which all these enzymic secretions are produced are very finely controlled. They are very expensive to make in terms of energy and raw materials, and so it would be very wasteful to produce them all the time, even when there was no food to digest. And so the body has some very well designed automatic arrangements for sampling the foods as they are eaten and passed on, which ensure that exactly the right kind of juice is waiting in every part of the digestive tract for whatever food arrives. As soon as the food is digested the supply of enzymes is automatically switched off, so that there is very little waste of precious materials. It is, of course, beyond the scope of this account to describe the control mechanisms. Suffice it to say that they are operated partly by nerve reflexes which signal the imminent arrival of food, and partly by special hormones produced in various parts of the gut wall. The best secretion is affected even by psychological factors, so that pleasant company and surroundings, attractive appearance of the food, and an eager anticipation of it all make for good digestion and good health. These psychological factors are all capable of proper scientific investigation and proof. The poor health of those who habitually and irregularly bolt unpalatable food is probably due to such factors as these. So is the failure of appetite in the depressed, the anxious adult, or the scolded child.

Nearly all the digestion which has been described occurs in the stomach and upper part of the small intestine (the duodenum, jejunum, and upper ileum). Almost all absorption of the products of digestion occurs in the small intestine which is long and intricately folded to give it a large surface area for this purpose. The colon, or large intestine, is adapted for conserving water, by removing it from the residual waste material. This has then to be eliminated, and being rather dry its passage has to be lubricated by suitable secretions of mucus.

Constipation. Here, perhaps we had better mention the morbid question of constipation, about which so many people are obsessed and hold such pronounced views. First of all, what is it? For some people it is entirely normal only to pass motions about once or twice a week. For others the normal frequency is once or twice a day. What is abnormal? The answer is that the only thing worth worrying about is any pronounced change of bowel habit, particularly in middle-aged and older people. By a change is meant a change from that individual person's normal routine. Such a pronounced change—either in the direction of constipation or diarrhœa—is worth consulting your doctor about if it persists for more than a week or two. Otherwise, forget your bowels and leave them to work naturally as they know best. Many believe that constipation is the root of all evil, that it causes a mysterious condition known to them (although, alas, not to doctors) as "auto-intoxication." Sedulously fostered by the manufacturers of patent medicines, their beliefs range from the notion that headaches, spotty skin, muddy skin, and tiredness are caused by constipation, to the more extreme idea that the whole system is being poisoned and that, if the bowels do not work, the individual will shortly die. Of course, all this is the merest rubbish; for, as Professor Samson Wright, whose *Applied Physiology* is one of the most famous of medical text-books, has pointed out, there is no such thing as absorption of poisonous products from the bowel. There is no such thing as "auto-intoxication." "The symptoms of constipation," he writes, "are largely due to distension and mechanical irritation of the rectum." It has been shown that an enema removes these symptoms *immediately*, which would not be the case if they were due to poisons in the blood, and exactly the same symptoms can be produced by packing the rectum with cotton-wool. Wright mentions the case of a man who went for just over a year without a bowel motion, and at the end of that time, although his abdomen was distended and he felt some discomfort, he was not noticeably ill. Needless to say, telling these facts to the purgative addict will only make him annoyed, but it is as well to note that if no known diseases are due to constipation (although constipation may be a symptom of another disease), the regular use of purgatives *can* cause disease.

Constipation should be treated first by diet containing plenty of roughage—bran and oatmeal are excellent—plenty of stewed and fresh fruits, and at least three pints of fluid should be taken daily. Failing that, one of the best things to take is a proprietary product prepared from senna pods. Never to be taken regularly are liquid paraffin, castor oil, preparations of aloes, Epsom salts, and all the other dreadful stuff that people swill down.

Œsophagus.

The œsophagus, or gullet, is more than a simple tube for taking the food from the mouth to the stomach. It is normally closed except when swallowing, and the act of swallowing is very complicated. When the material to be swallowed arrives in the back of the throat there is an automatic mechanism which opens the top end of the œsophagus to receive it, and from then onwards everything happens automatically. The next portion of the tube opens and the top closes strongly, so that the food (or drink) is propelled forcibly down the next segment. Then the part below this relaxes and the material is squeezed further downwards and so on until it arrives in the stomach. This squeezing (or milking) action is akin to the action known as peristalsis which propels contents in other parts of the gut. Thus when you see someone swallowing a glass of beer very quickly in warm weather, it is not going "down the hatch" under the influence of gravity, however much it may look like it. It is perfectly

possible to swallow the same, or any other liquid, standing on your head. Getting into that position is the only difficult part. Sometimes this complicated swallowing mechanism gets out of order, leading to difficulties of swallowing, or *dysphagia*. Another disorder known as *hiatus hernia* occurs at the lower end of the œsophagus as it meets the stomach. At this point the œsophagus has to pass through the diaphragm, the sheet of muscle which separates the chest from the abdomen. The muscular fibres of the diaphragm are normally arranged in a ring around the œsophagus. These help to keep the lower end shut, so that the acid contents of the stomach do not regurgitate upwards, causing inflammation (*œsophagitis*) or heartburn. A hiatus hernia is when muscle fibres get slack, and the upper end of the stomach can even slide upwards into the chest. People with hiatus hernia get heartburn after meals, and particularly when they bend down or lie down. Except for very severe forms, which need surgical repair, the treatment is to eat less at a time, reduce the acidity with a suitable antacid and reduce weight, so that the weight of the abdomen does not press upwards so much. The other disease of the œsophagus, quite unrelated to the above, is *cancer of the œsophagus*, the cause of which is still unknown in most cases. When cancer occurs in the wall of any tube, it will often encircle the tube and gradually narrow the way through. This is what happens in the œsophagus, leading to difficulty in swallowing, particularly solids. It is a condition, usually, of rather elderly men, although it is sometimes associated with a special form of severe anæmia in women. Treatment is in some way to keep the passage open, either by transplanting a new tube, or more usually, by removing the constricted piece and joining up the remainder.

The Stomach and Duodenum.

By far the commonest diseases of the stomach and duodenum are *gastric ulcer* and *duodenal ulcer*. They are actually the same condition in two different sites and are often classed together as *peptic ulcer* or *acid-peptic disease*. The ulcers, which are rather like sores on the lining of the stomach or duodenum, may be "acute" or "chronic." Acute ulcers tend to be small and there are often several of them. Chronic ulcers are usually single. They may be small, or they may be several centimetres across. Chronic ulcers smoulder for months and even years, like a sore which will not heal, and a great deal of scar tissue forms in their depths. Thus they may in time erode their way right through the wall of the stomach, destroying all its layers, and begin to eat into surrounding structures like the pancreas or liver. The fact that they do not perforate more frequently is due to all the fibrous scar tissue which is formed during the slow eroding process. Healing of such a destructive ulcer is nevertheless common, and the great problem is how to help the natural healing process to win against the ulcer's tendency to erode. Better still would be to discover the cause, and prevent it happening in the first place. This extremely common affliction is confined to the human species and has been known since the earliest times. It does not vary very much with diet or with social class. Although occurring at all ages, it usually begins between the ages of twenty and forty, and is most commonly found in men between forty-five and fifty-five. Gastric ulcer is four times, and duodenal ulcer ten times more common in men than in women. It is always due to an inability of the lining to stand up to the normal digestive activity of the stomach contents. These are normally acid and contain a powerful enzyme for digesting proteins. Again it is perhaps more surprising that we all do not digest our own stomachs, rather than that some unfortunate people do digest small areas slowly. In certain abnormal conditions when the stomach stops making acid, ulcers always heal. However, some ulcers occur without excessive secretion of acid and many heal without the acid being neutralised with antacids. All this points to the main trouble being in the response of the lining to acid rather than to the acid itself. Nevertheless, the most effective treatment at present known involves regulating gastric secretion, and particularly its acidity. It is also known that peptic ulcers are more common in people whose occupations involve administrative and professional responsibility, competitive effort and nervous tension, long periods of anxiety or frustration. Presumably the higher nervous system influences these events by the same nerves, which normally help to control secretion.

The main symptom of peptic ulcer is pain, and this usually responds well to proper doses of antacids. Many different varieties are available and a lot of money is made from selling them. When indigestion persists for longer than a few days it is always better to see your doctor so that a proper diagnosis can be made and the best remedies begun. Many other causes exist for similar pains, and you should not try to make the diagnosis yourself. It may be necessary to analyse your gastric secretions in the hospital laboratory. Almost certainly you will have a special X-ray examination, and since the stomach cannot easily be seen on a normal X-ray, they will have to show it up by making you drink a white material containing barium. This will be seen as a silhouette of the stomach and duodenal contents. Searching for an ulcer this way is a highly skilled matter and is performed by doctors specially trained in radiology.

No drugs are known (although many are tried) which influence the duodenal ulcer's natural course. The stomach (gastric) ulcer is much more treatable with drugs. The general treatment of peptic ulcer is designed to relieve symptoms, heal the ulcer, and prevent complications (see later). Some rest and sedation may help to deal with the psychological influences at work. A special diet may be required. If certain foods cause discomfort they will naturally be avoided, but there is no evidence that any particular foods, like coarse or highly seasoned things retard, or that a soft, bland diet enhances healing. The era of sloppy, milky diets is almost over, for which countless ulcer sufferers will be profoundly thankful. Suitable antacids will be prescribed. Once an ulcer is diagnosed, the time has come to stop treating yourself with antacids from the chemist's counter, and to take the ones your doctor decides are best. Smoking should be stopped by ulcer patients (as, indeed, by everyone else, but that is another matter) because it inhibits healing. Alcohol tends to increase acid secretion and should be avoided. It is also *extremely important* to avoid taking any form of aspirin, even in quite small amounts, since this can lead to very serious bleeding from the ulcer. The ulcer patient should be warned that hundreds of proprietary preparations contain aspirin and all of them are dangerous for him. Search for the formula in small print on the label before taking any remedy, looking particularly for acetyl salicylic acid—the correct name for aspirin. Even some widely sold "hang-over" remedies which are sold for "upset-stomach" contain large quantities of aspirin. Some of the patients with "upset stomach" are, of course, ulcer patients, and some even die of haemorrhage following the ingestion of aspirin.

The main complications of peptic ulcer are bleeding, perforation, and a narrowing of the pylorus, or lower part, known as *pyloric stenosis*. Bleeding is caused by the eroding ulcer eating away at one of the many blood vessels in the stomach or duodenal wall. It leads to the passing of "altered" blood in the stool (*melaena*), or to the vomiting of blood (*hæmatemesis*). When the initial bleeding occurs, the patient may feel suddenly faint, and a little later will notice the black, tarry colour of his stool. This is sometimes confused with a similiar colour when the patient is taking iron. Peptic ulcer is not the only cause of this very serious hæmorrhage, which constitutes a hospital emergency whatever its cause. The treatment, like that of every large hæmorrhage, is blood transfusion which must be continued until the bleeding stops, or until the patient is sufficiently fit for surgery, should that be deemed necessary. Perforation is perhaps the most serious complication of peptic ulcer, leading to the spilling of stomach contents within the abdominal cavity. Treatment is invariably surgical, either

the closure of the perforation or the partial removal of the stomach.

Surgical removal of part of the stomach is often the only way to treat a peptic ulcer which has had its chance to heal in other ways. It is tempting for the patient to " have it out and done with, " but the time for surgery is a matter of fine judgment. So many ulcers heal by medical means if you give them a chance, and operations are for those which persistently refuse, or which become complicated.

Stomach Cancer. The stomach is a fairly common site for primary cancer. There is no known reason for this, and it is particularly important to stress that we know of no connection whatever between the peptic ulcers which have just been discussed and cancer. Stomach cancer used to be the commonest cancer of men, but the current rise of lung cancer has pushed it into second place. There are some strange geographical differences in its distribution. For example, it is much commoner in Japan and Scandinavia than in England or the U.S.A. It is difficult to see any reason for this in dietary habits. In Wales it causes three times as many deaths as in South-East England. All this is very puzzling, as is so much of our information about cancer generally. One of the main problems with stomach cancer is that it often causes the patient no inconvenience and thus produces no symptoms of note until the disease is far advanced and it is difficult to do much. Treatment is by surgical removal of the growth, and even in the most advanced cases a great deal can often be done to make the patient more comfortable.

The Small Intestine.

The small intestine runs from the stomach to the cæcum and comprises the duodenum, jejunum, and ileum in that order. On a more cheerful note it may be remarked that it is very rarely the site of cancer. Its main problems arise in connection with defects in absorption mechanisms, with obstructions, and with a strange inflammatory condition known as *regional enteritis*. Most obstructions are due not to blockages of the tube, but to failures of peristaltic propulsion, the process which is briefly described above under " œsophagus." Such a failure is called *ileus*. When peristalsis stops for any reason, the result is severe dehydration and loss of important chemicals like sodium and chloride from the body. This is because about two gallons of fluid enter the small intestine each day in the form of digestive juices, and all of this has to be pushed onwards to be reabsorbed into the system at lower levels. If peristalsis fails, this bulk of fluid remains in the small intestine, or is vomited. In both cases it is lost to the body itself, leading to serious dehydration and illness. Treatment is by very careful replacement by transfusion of the fluid and the chemicals lost, and by removal of the trapped fluid within the intestine through a tube threaded down through the mouth.

Regional enteritis or *ileitis* is sometimes known as *Crohn's disease.* It is a very mysterious condition in which the normally supple wall of the small intestine becomes inflamed and gradually replaced by thick fibrous scar tissue, so that it looks and feels like a thick garden hose. Loops of inflamed gut stick together, and channels open between them, and if the disease progresses a mass of adherent, thickened intestine results to which everything in the neighbourhood also adheres. However, for some unknown reason some cases do not progress downhill in this way and get better spontaneously. Surgical treatment is necessary for the majority, however, particularly those with advanced disease leading to complications such as obstruction or perforation. Sometimes an early case can be resolved by cutting out the length of affected gut, although recurrences are unfortunately common.

Appendicitis. This must be one of the best known surgical diseases of the intestinal tract. The appendix is a narrow, blind-ended side tube attached to the cæcum near the end of the small intestine. Appendicitis is when it becomes obstructed, or infected, or both. From its position it is almost predictable that it will get obstructed sooner or later by pieces of fæcal matter which pass its entrance and which are normally infected. The surprising thing is that it does not happen more often. Once this has occurred, however, a closed abscess forms, and as the abscess distends the appendix, it first weakens its wall, making it gangrenous, and then bursts into the abdominal cavity causing *peritonitis* (see later). It would be useless and misleading to describe the symptoms of acute appendicitis in detail, since it is difficult even for experienced doctors to distinguish them from those of several other conditions. Suffice it to say that any severe, persisting pain in the abdomen, whether continuous or intermittent, whether associated with diarrhœa or not, should lead the sufferer to a doctor for a quick diagnosis. Germ-killing antibiotics are useless against appendicitis, and any laxative is extremely dangerous as it may cause an acutely inflamed appendix to perforate.

The Large Intestine or Colon.

The two main serious diseases of the colon are ulcerative colitis and cancer in its various forms. *Ulcerative colitis* is yet another mysterious disease in which severe ulceration of the lining of the colon gives rise most frequently to diarrhœa with the passage of blood and mucus. In fact it can be like dysentery, and it has often been considered to be due to some form of infection. Unfortunately no particular germ can routinely be found in these cases, and the situation is endlessly confused by the presence in the normal bowel of lots of different germs anyway. Nevertheless the ulcerated lining of the bowel certainly does get infected by the germs normally present, and this makes the disease worse. Therefore germ-killing antibiotics are often helpful in alleviating symptoms and can lead to an earlier settling down of the condition, although not to a cure. It has long been known that certain kinds of psychological upset are often associated, but here again the disease is so unpleasant for the sufferer that he is to be forgiven some despondency as a result of, rather than as a cause of, his troubles. It is also suspected that ulcerative colitis may be an auto-immune disease; that is it may represent rejection by the patient of his own colonic lining in a manner somewhat comparable to the tissue rejection which often follows organ transplantation. Some of the more alarming complications are perforation through the wall of the ulcerated bowel, and sometimes massive hæmorrhage occurs. Medical treatment takes the form of keeping the patient in good physical condition in spite of his fluid and blood loss and his frequent lack of appetite. Surgery is often required to relieve obstruction, deal with perforation, remove chronically affected parts of the bowel, etc.

Cancer of the Colon and Rectum. This is another very common form of cancer, which can often be completely cured by surgical removal of the growth provided it is caught in the early stages before it has spread. The commonest symptom is a change in bowel habit, either towards constipation or, more often, towards diarrhœa, in the second half of life. There may be rectal bleeding, or the passage of mucus, and there may be abdominal pain. We cannot too often repeat that any such change of bowel habit, or any unexplained bleeding from any site should lead the patient promptly to his doctor.

Diverticulitis. Some people have small pockets or sacs in the wall of the colon known as diverticula. A minority of these sometimes get inflamed, and this is *diverticulitis.* Occasionally perforation occurs.

Hernia or Rupture. This is a condition in which abdominal contents, usually a loop of intestine, protrude forwards through the muscular

wall of the abdomen. The wall consists of a sheet of muscle fibres running in several directions. They normally become tense when we cough, or strain, or in getting up from a recumbent position. There are places in the groin on each side where there is a way through the muscle for the spermatic cord in the male. In many men a weakness can arise at this point, and if it persists, the way through may enlarge and allow loops of bowel to emerge from behind the muscle sheet to appear as a lump under the skin of the groin. On relaxation the lump can be made to disappear by pushing the contents back the way they came; and they will re-emerge when the patient strains. This is an extremely common complaint in men, and it should be treated by an operation in which the muscle wall is repaired. Some men, however, neglect to have their rupture treated until one day it proceeds to "strangulate." This is the term used when the muscle tightens around the neck of the protruding loop of bowel, cutting off its blood supply. From then onwards the loop becomes gangrenous and the intestine is obstructed by having a part of itself nipped outside the abdominal wall. The patient is in severe pain, vomits continously, and quickly is liable to get into such a poor condition that surgical relief is difficult. It is therefore a surgical emergency, and it would have been better to have had the relatively simple repair operation earlier and at leisure. Hernia in the region of the groin is of two types: *inguinal hernia* and *femoral hernia*, the difference between them being technical and of no consequence to the patient. They nearly always occur in men. Other types of hernia less frequently occur in both sexes. *Incisional hernia* is when the muscle wall has been weakened at the site of an old abdominal operation and has failed to heal properly. *Umbilical hernia* occurs owing to the natural weakness of the abdominal wall at the navel, and is so common in babies as to be almost normal. When a baby cries and thereby puts a strain on his abdominal wall, a lump often appears in the region of the navel, and this can be very alarming for the parents. They should of course show it to their doctor who will nearly always be able to reassure them. It is self-healing without operation in the majority of cases.

Peritonitis. The cavity of the abdomen in which the intestines and other organs lie is called the peritoneal cavity, and it is lined by a thin membrane called the peritoneum. When this becomes inflamed the condition is a serious one and is called *peritonitis*. Inflammation may be bacterial, as occurs following a burst appendix and the spillage of bacteria and pus in the cavity. It may be a sterile peritonitis as often follows perforation of a peptic ulcer, when the inflammation is caused by the acid contents of the stomach. It is always very dangerous, probably because of the large surface area afforded by the peritoneum for the absorption of inflammatory toxins.

Hæmorrhoids are simply varicose veins in the rectal and anal regions. They are very common, and are caused probably in about equal degrees by inherited weakness of the veins, strain such as heavy lifting, and constipation (this is one of the very few conditions in which constipation may do some damage, due to the mechanical pressure of hardened fæces in the rectum on the veins). Pregnant women are liable to develop hæmorrhoids or "*piles*," as they are commonly called, owing to the pressure of the baby's head in the pelvis. Hæmorrhoids may be external or internal, the former being in the anal region below the sphincter, the latter in the rectum; the two usually go together. There may be no symptoms, but the veins are liable to bleed, to get thrombosed (*i.e.*, a clot forms within) or to become infected. When clotting or infection occurs the piles enlarge and tend to be pushed out through the anus during defæcation, when they form extremely painful external swellings. Treatment in simple cases may be by the use of suppositories—cones of a firm grease containing suitable medicaments which are inserted in the rectum—in other cases the veins may be injected, as with varicose veins of the leg, in order to close them, but when there is much bleeding, thrombosis, infection, or interference with bowel movements they should be removed surgically.

DISEASES OF THE LIVER

The liver is the largest organ and has such a wide variety of known functions (to say nothing of the unknown) that it is also one of the most complicated. Nearly all of its functions are biochemical, and it is often called the laboratory of the body. Medical students, when asked to enumerate the functions of the liver, usually stick at about twenty-five, nearly all of them to do with general metabolism: that is the biochemical processing of substances taking part in structure or as body fuel. For example, the liver makes proteins from the amino-acids absorbed from the gut, and breaks down amino-acids and manufactures a waste product (urea) from them. It stores carbohydrates as glycogen, and conducts many of the processes necessary to turn carbohydrates into energy. It manufactures prothrombin with the help of vitamin K, and this is essential for blood clotting. It makes bile and secretes it into the gall bladder and bile ducts (*see later*). The three main constituents of bile (cholesterol, bile pigment or bilirubin, and bile acids) all have to be processed, or metabolised, in the liver during the production of bile. Vitamin B_{12} and iron is also stored and dealt with there, and these are involved in preventing various forms of anæmia (*q.v.*); and in addition to all these things the liver is the place where harmful substances, both from within the body and from outside it, are dealt with and rendered harmless. This last function of "detoxication" is often accomplished by making the offending molecules suitable for rapid excretion by the kidneys, or by altering their chemical shape to make them harmless.

Nearly all of these very different things are done by one single type of cell: the liver cell, and it is one of the remarkable features of the design that this cell can be so versatile. There also have to be some very efficient transport systems in the liver, in addition to the usual blood supply and venous drainage possessed by all other tissues.

One of these is the "portal venous system." Whenever a substance is absorbed across the gut wall from any part of the intestine into the interior of the body it enters the special draining blood vessels of the portal system, which are arranged throughout the length of the digestive tract. All these veins eventually unite in the main portal vein which enters the liver. Everything absorbed from the gut is therefore taken first to the liver to be processed. After this the products are carried away from the liver in the ordinary veins to the heart, and are distributed to the rest of the body by the arterial system. The liver has arteries of its own by which it receives oxygen and nutriment like any other tissue. The fourth transport system collects the bile as it is formed within the liver and delivers it to the gall bladder and bile ducts, which eventually drain it into the duodenum.

Portal Hypertension means high blood pressure in the portal venous system, and is the usual accompaniment to *cirrhosis* (*see later*). When the terminations of the portal veins in the liver are strangled and obstructed by cirrhotic disease, this tends to blow them up, or dilate them with with blood. There is a natural escape route for the portal blood where the lower end of the œsophagus or gullet joins the upper end of the stomach. At this place some of the portal veins draining the stomach are connected with the ordinary veins draining the œsophagus so that when pressure rises in the portal system, blood tends to be diverted into these connecting veins, and they in turn become dilated, or varicose. Trouble begins when these dilated connecting veins, which bulge inwards into the œsophagus, are damaged by food particles passing across them and bleed severely into the stomach. The patient vomits large quantities of blood (*hæmatemesis*) or passes tarry altered blood in the stool

(*melaena*). The other main cause of these is the bleeding which occasionally accompanies peptic ulcer (*q.v.*).

A second complication of portal hypertension (and hence of cirrhosis) is *ascites*, in which large amounts of a lymph-like fluid accumulate in the abdominal cavity. The fluid contains a great deal of precious protein and salt which is lost to the body economy. Ascites also sometimes accompanies cancerous deposits in the abdomen.

Jaundice means being yellow because there is too much yellow bile pigment circulating in the blood, and there are three main possible causes for this. The term "yellow jaundice," like "gastric stomach" is therefore unnecessarily redundant: there is no other kind.

Bile pigment comes from broken-down red blood cells, which normally come to the end of their time after existing for about 120 days. The breakdown products of red cells can always be found in the blood of normal people, but there is normally insufficient colour to show. Abnormal amounts of colour build up quite logically in any of the following three circumstances:

(1) If too many red cells are being destroyed and even the normal liver cannot deal with the amount of bile pigment produced, it piles up in the blood, and *hæmolytic jaundice* is the result. The expression simply means jaundice due to (abnormally large) red-cell destruction.

(2) If the liver cells are themselves sick and unable to cope even with the normal amounts of pigment from normal red-cell destruction. Here too the pigment will pile up and cause *hepatocellular jaundice*, or liver-cell jaundice.

(3) If the bile ducts carrying bile away from the liver are blocked, then bile will pile up behind the blockage and re-enter the blood stream, causing *obstructive jaundice*. In this case the rate of red-cell breakdown is normal, and the liver cells are normal: at least for a time.

It is enormously important for the treatment of jaundice for the doctor to diagnose its type correctly, since the treatment varies from surgical relief of obstruction to the medical treatment of viral infection or of excess red-cell destruction.

The so-called differential diagnosis of jaundice is often exceptionally difficult, and sometimes requires some very sophisticated laboratory tests and X-rays. At other times it is extremely easy and is obvious from a cursory glance at the urine and the stool. In any case all jaundice is a highly technical matter for the doctor who must be consulted early.

There is a special jaundice of newborn babies which resembles hæmolytic jaundice and can occasionally have serious consequences for the developing brain (*kernicterus*) if it is allowed to become too severe. When this is threatened, steps are taken to reduce the level of circulating bile pigment by replacement of the baby's blood or by other means.

The commonest cause of hepatocellular jaundice is infective or viral hepatitis. Obstructive jaundice is usually due either to blockage by gallstones (*q.v.*) or by a lump pressing on the bile ducts from an adjacent cancer. This can often be quite satisfactorily relieved by surgery.

Infective Hepatitis. There is a group of disorders affecting the liver which are caused by viruses. The incubation period is often very long, and the sickness and other debility caused is often quite severe and prolonged. One variety, known as serum sickness, is now much less common than a few years ago. It used to be transmitted by using the same needle for injections into several different people, or from transfusing contaminated blood. A greater awareness of the problem, and the use of disposable needles and syringes has cut down the incidence.

Cirrhosis. There are many different kinds of cirrhosis, the commonest of which has already been mentioned under *portal hypertension* above. In all cases, liver cells are slowly poisoned and are killed off over a long period of time. In response to this, the surviving liver cells undergo cell division, trying to make good the numbers lost, and at the same time fibrous scar tissue replaces the damaged tissue throughout the organ. The result is a hard, knobbly liver. The many "knobs" are spherical areas of regenerated new cells, and they are separated by thickened bands of scar tissue. All of this destroys the normal architecture and leads to the portal hypertension and ascites mentioned above. In some countries (*e.g.*, France and the United States) excessive alcohol is the main cause of the original liver damage which starts it all off. In others (*e.g.*, Bantu South Africa) it seems to be nutritional starvation of the liver. In England much less than half the cases are due to alcohol, and many are thought to be due to a previous episode of infective hepatitis (*q.v.*), but this is not certain. Infective hepatitis is quite common but cirrhosis is comparatively rare. So that the great majority of people do not progress from one to the other. One day soon the treatment for advanced cirrhosis will be to replace the liver by transplantation, but there are still many problems to overcome before this can become routine.

Cancer of the Liver. Cancer of the liver is quite common, but it is nearly always cancer which has spread in the blood stream from other parts of the body. The liver is a favourite site for such secondary deposits, since it has a large blood supply and will receive a generous helping of anything being carried. It is also a very "fertile soil" for the cancer seedlings to grow in. Primary cancer of the liver is uncommon, and only occurs in a few cases of pre-existing cirrhosis.

Gallstones. These are "stones" formed by some of the major constituents of bile coming out of solution and forming solid bodies. They are very common, and often cause no trouble at all. When they do, it is usually a cholicky intermittent severe pain. This is due to the muscular walls of the bile passages contracting in an effort to expel an obstructing stone into the duodenum. The second common trouble arising from gallstones is obstructive jaundice, described above. It is small consolation to gallstone sufferers that the stones are often very pretty, often being composed of beautiful cholesterol crystals coloured by varying shades of bile. If they contain calcium they will be visible on an X-ray. Otherwise they are not seen. Stones often occur in conjunction with inflammation of the gall bladder, known as *cholecystitis*. The treatment for gallstones is to remove them surgically together with the gall bladder if they are causing persistent symptoms. Ways of avoiding surgery by dissolving them in substances taken by mouth are under investigation.

The Pancreas.

This is a soft, elongated gland lying behind the stomach; it is about 5 in. long and 2 in. wide. Within its tissues lies the duct, which, when it leaves the pancreas, passes into the duodenum near the point of entry of the bile-duct. This duct transmits the juices containing enzymes which aid in the digestion in the small intestine. The pancreas, however, has two main functions: not only does it manufacture these important digestive juices, but in certain specialised areas, known as the islets of Langerhans, it manufactures insulin, the hormone which makes it possible for the body to utilise sugar. *Diabetes mellitus* or ordinary diabetes is a chronic disorder usually caused by a deficient secretion of insulin. The unused sugar accumulates in the blood and acts as a poison, which, in extreme cases, sends the patient into coma and may—indeed, in former times, usually did—result in death. The treatment of diabetes was revolutionised by the discovery of the hormone insulin by Banting and Best in 1921. On the whole, diabetes is more severe in young people than in the elderly, but with correct treatment it is possible for all cases to lead a perfectly normal life except for dietary restrictions and insulin injections. Not to be confused with *Diabetes insipidus* (P43(2)).

DIET.

When considering diet, and the effect it has on our health and well-being, there is more to it than just the things we eat. We must also know about what our body does with the food, and it would be unscientific not to acknowledge the effects of our psychological make-up and our nutritional beliefs on what we eat, what we do with it, and how well (or ill) we feel as a result.

For example, a deep-rooted conviction that brown eggs or free-range poultry are better for us than white eggs or intensively reared birds is entirely unsupported by any evidence. However, if we believe such a thing sufficiently, we will not only eat the "better" ones, but we will feel happier and more secure afterwards, and this is likely to make us healthier. Food fads can occasionally be dangerous, as when extreme vegetarians become ill through lack of certain vitamins (*e.g.* B_1) which are present only in the foods they exclude. But this is so rare, even among strict vegetarians, that such danger can virtually be ignored. On the whole (and vegetarianism is probably a good example of this) food faddism often leads to a sense of health and well-being in the believer, and should not be attacked by the rest of us for that. It is an accepted fact that personal misfortune, even when it is severe, is more easily withstood by those with strong religious conviction than by others. In the same way, a firm attachment to a theory of what is good for you can produce a feeling of well-being and genuine good health, when another person on exactly the same food intake will not feel so fit. These factors—religious belief, food faddism, or the bedside manner of a kind or persuasive doctor—are commonly dismissed by free-thinking people because they are not "true" or "real." All three, however, can materially affect our health just as can a shock, a personal tragedy or being in love. The trouble starts, and the magic ceases to work, when adherents declaim their beliefs as *ex cathedra* truths and expect the rest of us to swallow them as wholly (or holy) as they do.

Thus there are genuine *facts* about food, and fallacies too; and as well as these there is a no-man's-land between in which one man's fact is another man's fallacy.

The basic constituents of any diet are protein, fats, carbohydrates, water, vitamins, minerals, salts, and indigestible roughage. All are chemicals whose structure and function are reasonably well understood. Even the mystical differences between fine table wines, so beloved of the connoisseur and gourmet, are reasonably well understood in chemical terms. Perhaps that is a pity.

Much nonsense is talked, especially by nutritionists, about minimal daily requirements. In general terms, however, requirements can be described in terms of how many calories there are in the total intake of proteins, fats, and carbohydrates per day, and how these are distributed between the three classes of food. The other substances mentioned above are only required in trace or small amounts except for water; and roughage is only required as a mechanical stimulus to bowel movement.

During the process of digestion (described on P34–5) all proteins are split into their constituent amino acids; all carbohydrates are split into their constituent simple sugars and most fats are converted into fatty acids and glycerol. At this stage, and not until this stage, all these simpler building bricks derived from the three classes of food are absorbed into the body proper, and taken to the liver and other tissues. Here they are "metabolised." That is to say they are either burned as fuel for the various processes of the body; or they are built up again into proteins, fats, and carbohydrates of the special kinds the body needs. They will either be used to rebuild structures suffering ordinary wear and tear or they will be stored. Many of them will be converted into a different class from the one they came from when they entered the body. For example, excess carbohydrate is converted into fat; or if there is a shortage of carbohydrate, some will be made out of the protein amino-acids which would normally have been used for tissue growth and repair. Thus it is only a generalisation to say that dietary carbohydrates are fuel and proteins are for building bodily structure. The body can convert one into the other, and spoil the calculation.

There is a great deal of confusion in people's minds about *energy*, and that is why the word *fuel* has been used above in connection with carbohydrates. The lay person uses energy as a term meaning something which allows us to leap about, running and jumping and skipping and dancing, and which keeps us from getting tired and run down. Thus, the food industry tells us, we need potatoes or breakfast cereals for these activities or for a hard day's work. This is a deliberate commercial confidence trick, and the scientist is largely to blame. He originally handed out the word energy to an eager food industry and an unsuspecting public, forgetting to explain that he meant it in the strictly scientific sense of fuel for bodily processes. It simply is not true that more potatoes, or more cornflakes will make you more active. Indeed the reverse is the case, and after a certain point they will only be converted into fat and reduce your activity. The nutritionist measures energy as calories, which are units of heat, and it is certainly true that you must eat enough of these each day if you wish to remain alive, let alone active.

All the three main classes of food provide calories, and in an ordinary well-balanced diet about 15% are provided by protein. Carbohydrates produce most of the remainder. Each gram of fat contains about twice the calories of a similar quantity of carbohydrate. We simply eat less fat than carbohydrate, because fat has a "high satiety value." It takes away the appetite for more. Proteins are mostly found in meat, fish, eggs, cheese, and milk. However, there is quite a lot of protein in many predominantly starchy foods like bread, and such grains as wheat rice, and corn. Carbohydrates are mainly found in bread, potatoes, sugar, pastry, sweets, and so forth. That is one of the words which fortunately seems to be used by both scientists and laymen in much the same sense.

Some substances are absolutely essential to the body if life is to continue, even if they are only needed in trace amounts. These are substances which the body's own factories (like the liver) cannot make for themselves, even if they are provided with the correct ingredients. Unfortunately these essential constituents were given a system of names which grew, like Topsy, as they were discovered, and which has stuck due to common usage, even though more recent knowledge has made a nonsense of most of the words. One whole group of such substances is the *vitamins*. All of these, by definition, are essential and have to be provided for the body in the diet. Vitamins are another gold-mine for the food and pharmaceutical industry. The public know that scientists have discovered these magic substances, only tiny amounts of which are required to keep people healthy. Starting with that piece of "magic" it is not difficult to mislead people into two sorts of erroneous conclusion. The first is that all signs of minor ill-health and tiredness (from which we all suffer at times) are due to lack of these vitamins; and secondly that extra vitamins are the key to "extra" health. The truth is that no one in England who is eating a normal diet is short of vitamins in it; and there are no dividends in "extra" health for taking vitamins above the normal daily intake present in food. It simply is not true that extra vitamin C or D gives protection from colds and other winter ailments. The fate of the extra vitamin intake, however expensive, is the same as the fate of anything else the body cannot use: it finds its way expensively into the lavatory. The money would have been much better spent on wholesome meat or other non-fattening food.

Thankfully, most people buy food because they like it, not because it does them good; and provided they have normal dietary tastes they will usually get a perfectly adequate selection of the things we have spoken of as necessary for good health. The main danger in England is to have a surfeit and become overweight. In addition there are certain times of life when conscious attention should be paid to what is necessary. For example babies and nursing mothers have special dietary needs and will hear about them from their Health Visitor or from their Welfare Clinic or Doctor. Elderly people living alone are also prone to dietary deficiencies for reasons

ranging from poverty to loss of appetite or inability to look after themselves properly.

Recent surveys have revealed some interesting facts about people's attitude to food and their knowledge of it. For example, half the people asked knew that meat was a source of protein, a third mentioned eggs and a fifth cheese, fish, and milk. But practically no one knew there was protein in bread. Yet in England about a fifth of our daily protein intake comes from bread, and nearly a third from cereals as a whole. Fish is well known as a source of protein, but did you know that on average we only obtain 4% of our daily protein from fish—less than we get from potatoes (5%)? No one seems to know that potatoes are an important source of vitamin C, although fruit and vegetables are well-known sources. Calcium is recognised in milk, but most people forget its presence in cheese. Most people are very confused about iron. Why does everyone think it is mainly in green vegetables, when these are really such a poor source? Are we indoctrinated by Popeye? For our daily requirement of iron we would each have to eat 2½ lb. spring greens or peas; or 4½ lb. of sprouts! In fact meat provides one of our best sources, and one-fifth of our daily needs is contained in bread.

Since most of the people who read *Pears* live in England let us return finally to our commonest nutritional disease, or our commonest form of malnutrition in these islands: obesity. Call it "being overweight" if you like, but acknowledge that it means being fat. Being fat is not only unattractive and unsightly but it is dangerous to health and carries a high mortality. Ask any life insurance company how they view your chances if you are overweight and you will find they are as worried about it as if you had high blood pressure, or smoke heavily. It is a particularly important cause of heart disease. However, it is very important to know exactly what we mean by fatness. Many girls who are not at all fat think they are, and this leads them to diet unnecessarily. On the other hand there are people who do not appreciate they are overweight. Here is a table which shows what your weight should be according to your height.

If you are overweight according to these tables you need to slim, and the question is how? Answer: by will-power. There is no other satisfactory method than to decide to eat less, and to eat as little carbohydrate as possible. For the time being eat as much meat, fruit, green vegetables, and as much fat as you like, but no sugar, starch, sweets, cakes, pastry, or biscuits, and no eating between meals. And cut down on beer and other alcoholic drinks. In case you are tempted to eat "slimming" foods, be aware that there is no such thing. There is nothing you can eat which will cause you to lose weight, in spite of what the advertisement says. In special cases doctors will prescribe tablets to suppress appetite, but they are too dangerous for general use without supervision, and they do not work as well as will-power. At the same time take more exercise. Walk to work. If you make a real and genuine effort for three months without success, you should ask your doctor for advice. Almost certainly you will have to admit you have not really tried. Good luck!

DESIRABLE WEIGHTS FOR MEN AND WOMEN ACCORDING TO HEIGHT AND FRAME, AGES 25 AND OVER

Men Height (with shoes on—one-inch heels)	Weight in pounds (in indoor clothing)		
	Small frame	Medium frame	Large frame
5′ 2″	112–120	118–129	126–141

NUTRITIONAL DISORDERS.

Nutritional Deficiency and Malnutrition.—Until quite recently a consideration of malnutrition would have merely led to an account of how too little food, or a deficiency of certain articles in the diet, produced deficiency diseases at the time of the restriction. For example lack of vitamins of various kinds gives rise to such diseases as rickets, scurvy, beri-beri, and pellagra; and an overall shortage of food to general starvation. These may be considered the immediate or concurrent effects of a poor diet. Modern nutritionists, however, are beginning to be concerned with two more kinds of nutritional disorders; and although the study of both kinds is in its infancy, both will be introduced in this account.

The first deals with the effects of comparatively small amounts of harmful constituents in our diet, introduced either voluntarily or involuntarily, and consumed for a long period of time; and the second with the lasting effects on our adult well-being of nutritional deficiencies in early life even though they have long since been corrected.

When viewed in this light, one or other of these three kinds of nutritional disorder may at this moment be affecting almost every individual in every part of the world, "privileged" or "underprivileged." Let us first define some terms.

Undernutrition, strictly speaking, means a state of affairs in which the quality of the diet is perfectly good. There is the correct balance of the various dietary constituents and all the necessary components are present: but there is simply too little of it. Many hundreds of millions of people throughout the underprivileged world are suffering and dying from this kind of undernutrition, and the simplicity of the problem must be appreciated: they simply need more food of the kind they are at present getting, and which can often be produced locally.

Malnutrition means an imbalance of the various constituents: a relative lack or excess of one or more of them. It usually leads to conditions which are, from the point of view of medical treatment, much more difficult to deal with. And therefore doctors often class them as "more serious."

The diseases of malnutrition range from the widespread protein deficiencies in other parts of the underprivileged world to *obesity* in our own better-off industrial countries, which is usually due to excess carbohydrate. Make no mistake about it: obesity (or being overweight) is a widespread disease of nutritional imbalance, and it kills. It is the commonest form of malnutrition in (for example) England and America today, and is a consequence of the sophistication of our diet in modern times. Between one-fifth and one-

tenth of the population of the United States is more than 20% overweight, and to be 10% or 15% overweight is almost the rule nowadays in people over thirty. There are high authorities in the world of nutritional science who attribute all this overfed malnutrition to the consumption of refined sugar, or sucrose. They say it is not only the amount of refined sugar we put in our tea or on our breakfast cereals, but also the amount in sweet cakes, biscuits, drinks, chocolates and sweets, and so forth. For some people it adds up to a phenomenal quantity each day. According to this school of thought we are not so much suffering from a surfeit of carbohydrates or starches, but from this single sugar, sucrose. It is interesting to reflect on the recent banning of the artificial sweetener, cyclamate, by many governments. This substance, having been used extensively throughout the world as an apparently harmless non-fattening substitute for sugar, was suddenly banned in America because in very large doses (equivalent to the amount taken in hundreds of cups of coffee per day for a long time) it was found to produce cancer in rats. It has never been shown to do humans any harm, whereas the effects of sugar in producing an overweight population, thereby indirectly kill tens of thousands of British people each year. This is a fascinating example of the difficulties confronting our legislators in making balanced judgments when deciding to ban a foodstuff, a drug, or an artificial fertiliser.

Much the most widespread form of malnutrition, however, is a variety protein-lack which is part of a collection of nutritional diseases known as *Protein-Calorie Deficiency*. In very large underprivileged areas of the world, the childhood population receives such an inadequate diet that children live continuously on the brink of nutritional disaster. It only requires a small extra restriction or stress to topple them over into one of the clinical conditions to be described. At this stage they cease to be merely hungry. They become nutritionally ill. Sometimes the force which produces the disaster is a community catastrophe like a famine, an earthquake, or a war. Sometimes it is a family catastrophe like the loss of a lactating mother or a parental delinquency. Parents abandon young children as often in Africa as anywhere else. Sometimes the clinical nutritional disease is unmasked by a common childhood illness like measles, or gastro-enteritis which the well-fed child would have overcome. The starved child reveals his malnutrition instead and frequently dies. When the precipitating cause of the "epidemic" of malnutrition is a war or other national calamity, our newspapers and television screens carry distressing pictures of thin skeletal, pot-bellied children, and the conscience of a few is touched. It is insufficiently realised that these scenes can be witnessed anywhere in the continents of Africa and Asia, and in large parts of Central and South America any day of the week in normal times. The war has not been the cause, but is only the precipitating factor which has revealed the chronic malnutrition in more children than would normally exhibit it openly.

Protein-Calorie Deficiency is a collection of different kinds of childhood malnutrition. Some are due predominantly to deficiency of protein and are collectively called Kwashiorkor, a West African word meaning "red-haired boy" (see below). Others are mainly due to a severe deficiency of overall foodstuffs and are called *Maramus*. But in any real-life situation the severe *mal*nutrition of Kwashiorkor exists side-by-side with all gradations between itself and the severe *under*nutrition of Marasmus, so that many intermediate forms of "marasmic kwashiorkor" are described. In kwashiorkor the child is typically listless, apathetic, whining, with a reddish discoloration of the hair, a peeling, scaly skin, and with much extra fluid in his tissues causing œdema. He is so listless as not even to be hungry. In marasmus the child is ravenously hungry. He is extremely thin and "starved" looking and is quite a different picture.

There is good reason to believe that even when protein-calorie deficiency is successfully treated, there will always be some lasting restriction of mental function, particularly if the malnutrition occurred as early as the first year of life. This is especially true in situations of appalling poverty in towns, where thousands of babies are not breast-fed because their mothers are at work. Many of them die. Some of them are no heavier than their birth weight at one year of age. Breast feeding in an underprivileged community is an essential insurance for childhood health and survival.

Two new avenues of nutritional inquiry were mentioned at the beginning of this section. The impact of very long continued intake of refined sugar over many years on our bodily health is an example of one of them. Scientists and others are also becoming alarmed at the effects of modern food additives when taken, even in small amounts, over a long period. These additives include colouring matter, decolourising chemicals, taste "enhancers," and so forth, which are present in everyone's diet in a "civilised community." We are as unable to avoid a constant dosage with them as if they had been added to our water supply. It is, however, difficult to strike a balanced attitude. It is one thing to suspect that these additives are harmful and quite another to prove it. Naturally if any of them are shown to produce harm in animals given reasonable quantities they are invariably withdrawn. But in practice it is extremely difficult for animal experiments to mimic the conditions of human intake, especially as the human life span involves eating the substance concerned in small quantities for several decades. Thus it is easy to postulate the harmful effects of monosodium glutamate (a very common taste enhancer) but practically impossible to prove the question either way. It is not sufficient to condemn "chemicals." All natural foods consist of chemicals, and so do we.

The other new topic in nutrition is more soundly based on animal experiment. It has been repeatedly found that if animals do not grow quickly enough at certain early periods of life, they not only become small, but they remain smaller than they should be even when they are subsequently given as much as they like to eat. This is true of all animals and birds so far studied. For example, if rats are suckled in large families it is found that they are smaller by the time they are weaned (3 weeks of age) than those suckled in small families. The interesting thing is that if they are then given as much as they want to eat for the rest of their lives, the small animals from the larger families never catch up to the others. Whereas if their growth is not restricted until later in their "childhood," full "catch-up" is possible soon after normal diet is resumed. In other words there is a critical time in early life when growth can be permanently affected. At the moment it is difficult to know whether the same is true of humans and, if so, when is our period of vulnerability. There is some suggestion that the corresponding critical period in humans is during the last part of gestation in the uterus, and the first year or so of postnatal life. This new idea may turn out to be very important for world nutrition. Since there will not be enough food for all the children all the time, it may become important to concentrate our aid to underprivileged countries on certain sections of the population only. It may be a good idea to see that pregnant mothers and small babies are specially fed. In this way we may be able to put off the periods of inevitable malnutrition until a time of life when it is recoverable. Such a plan would also go a long way to safeguarding the development of the brain which also occurs mostly at the same early time of life.

We shall now describe some of the better-known nutritional deficiencies, bearing in mind that vitamin deficiencies are virtually unknown in the better-off countries. No one in England need spend money buying vitamins, as has been emphasised in the preceding section. Vitamin deficiency can still occur, however, in elderly people living alone and not having a well-balanced diet. It also occurs for similar reasons in alcoholics, vagrants, etc., and very occasionally in small children.

Beri-beri is a group of diseases usually confined to the Far East where a diet of polished rice results in a poor intake of vitamin B_1 (thiamine). In one form there is oedema (*q.v.*); in another the peripheral nerves are affected leading to tingling

and numbness. A similar condition is occasionally seen in alcoholics and diabetics. Treatment is with thiamine, and with other vitamins too, since most sufferers are going short of more than one.

Pellagra is found among maize-eating populations and is due to a deficiency of several vitamins including niacin, another member of the B group of vitamins. There is dermatitis on exposed skin, and soreness of the mouth and tongue, with gastro-enteritis.

Scurvy is due to vitamin C deficiency. In children bone growth is affected. At all ages there is bleeding into the skin (bruising), impaired wound healing, mental depression, and anæmia. Most fresh fruit and vegetables contain vitamin C and a diet containing these prevents the disease.

Vitamin A deficiency is commonly found in children in some underprivileged countries. It causes permanent blindness, with thickening opacity and dryness of the whites of the eyes leading to ulceration of the eye. Beyond a certain stage, therefore, a child's sight cannot be saved. The only real hope is prevention, with an adequate diet.

Rickets, another disease of early childhood, is caused by deficiency of vitamin D. Bones are not properly calcified, and their softness leads to deformities of the legs and many other bones. Vitamin D can either be eaten in the diet or produced under the skin under the influence of sunlight. Therefore rickets commonly occurs when both the diet and the sunlight are inadequate. It was once very common in industrial England, and is still to be seen very occasionally there and in impoverished urban communities in the United States.

DISEASES OF THE ENDOCRINE GLANDS.

Glands are structures or organs which manufacture secretions (except for *lymph glands* which are not glands at all and should be called *lymph nodes*). The secretions are of two main kinds. The first are passed down tubes, or ducts, or are secreted directly into the hollow organs, and act locally. Good examples are the salivary glands which make saliva and pass it down ducts into the mouth for digestion of its contents and lubrication. These are *exocrine glands*. The second kind have no ducts, and secrete their product straight into the blood stream. This secretion is called a *hormone* and it is carried to all parts of the body by the blood where it acts at a distance on some remote part. These are the *endocrine glands* or *ductless glands*, and a number of them will be discussed in this section.

The first hormone, or "chemical messenger," was discovered by the British physiologist Starling in 1904, but the effects of removing some of the endocrine glands were known centuries before when removal of the male testes (castration) was practised to procure a form of manpower safe for the harem, to salvage a good male alto voice for the church choir, or to convert a rooster into a more eatable capon.

Anterior Pituitary.—Many of the endocrine glands do not act as separate autonomous organs in spite of their great differences. They are organised into a well-disciplined band by a "master-gland" called the anterior pituitary. Somebody once called it the "conductor of the endocrine orchestra" and the phrase is still repeated *ad nauseam* in students' examination papers. The pituitary, consisting of its two parts, anterior and posterior, is not much bigger than a pea and it sits right in the middle of the skull, centrally beneath the brain and joined to the brain by a short stalk. This astonishing tiny nodule of tissue produces at least eight important hormones.

One of these is *growth hormone*, which is necessary for normal growth, and also has an influence on insulin. An excess causes *gigantism* and *acromegaly*, often coinciding with diabetes, and too little results in a form of dwarfism. Three others, known as *gonadotrophic hormones* regulate the cyclical and other activities of the reproductive organs and lactating breast. Another, *thyrotrophic hormone*, regulates thyroid activity, *Adrenocorticotrophic hormone*, or *ACTH*, as its name implies, looks after the activities of another important endocrine gland, the adrenal cortex. And there are several others.

Hypopituitarism, including *Simmonds' disease* and *Sheehan's disease*, results from destruction of the anterior pituitary. It is extremely rare, and is usually associated with difficult childbirth involving very severe bleeding. There are disturbances of all the functions mentioned above, particularly thyroid and adrenal failure (*q.v.*) with upset sexual function. Treatment is by replacing the lost hormones.

Hyperpituitarism, including *gigantism* and *acromegaly*, results from over-activity of the anterior pituitary, and is usually due to a tumour or overgrowth of the gland. In acromegaly the growth hormone is produced in excess over a long period of time in an adult. This results in overgrowth of all the organs except the brain, and it is characteristic to find enlarged extremities—feet, hands, and jaw. In gigantism the same has occurred during childhood before the bones have stopped growing and the result is a person who may be 6 ft. 6 in. tall or more.

Posterior Pituitary. The posterior part of the gland is really a quite separate gland. The main hormone it produces is concerned with the excretion of urine by the kidney (antidiuretic hormone). Deficiency of the hormone results in *Diabetes Insipidus*, not to be confused with *Diabetes Mellitus* or "sugar diabetes." In diabetes insipidus, the patient produces enormous quantities of dilute urine. He consequently has a prodigious thirst and consumes astonishing quantities of fluids. Treatment is by replacing the missing hormone.

Thyroid. The thyroid gland in the neck secretes an iodine-containing hormone called thyroxine. Excess of it causes *hyperthyroidism*, *thyrotoxicosis*, or *Graves' disease*. Lack of it produces *cretinism* in the growing child or *myxoedema* in the adult. Thyroxine is concerned with the metabolic rate of cells throughout the body, or the rate at which they work, as well as with the proper growth of developing tissues, especially the brain. Too much thyroxine as in thyrotoxicosis leads to over-activity, warm sweatiness in an over-excitable patient whose pulse is rapid and who is eating ravenously to try to replace the wasted energy. In spite of his appetite he is very thin, and he often has bulging eyes for a reason not understood. Treatment is by drugs which neutralise the thyroxine or by cutting out some of the gland. A *cretin* is a child usually born with insufficient thyroid. He is destined to grow poorly, and to mental subnormality of a permanent and distressing kind. If the condition is diagnosed soon after birth treatment with thyroxine can avert most of the trouble. In myxoedema, thyroxine is deficient in an adult. They become slow in all their bodily processes, the hair thins and their flesh is puffy with a dry, wrinkled skin. Treatment is by thyroid replacement. *Goitre* simply means enlargement of the gland. It may be accompanied by overactivity or underactivity, or with little functional change. One variety (Derbyshire neck) occurs in areas short of iodine in the soil and drinking water.

Adrenal Cortex. The adrenal or suprarenal glands sit, as the name implies, one on top of each kidney. There are two distinct parts: the cortex or outside which secretes steroid hormones, and the *adrenal medulla*, or core, which secretes adrenalin. There are many different steroid hormones in the adrenal cortical secretion, which look after such divers matters as sodium and potassium balance, sexual function, the reaction of the body to stress, and the regulation of sugar levels. *Addison's disease* (not to be confused with Addisonian anæmia) results from adrenal cortical insufficiency, and is often due to destruction of the gland by tuberculosis. There is weariness

malaise, pigmentation of skin creases and mucous membranes. They are short of sodium and have excess potassium. Treatment is with cortisone (replacement of the missing hormone) and by extra salt by mouth for the lack of sodium. *Cushing's* disease is due to excessive adrenal cortical function, and sometimes also occurs in patients treated with cortisone for other purposes. They have a striking redistribution of fat in the face, neck, and trunk, with stretch marks similar to those acquired by most women during pregnancy. The facial obesity makes them "moon-faced," and female patients may suffer masculinisation with deepening of the voice and hirsutism.

Testis. The male testes, as well as producing sperm are also endocrine glands producing steroid hormones known as androgens. They are mainly concerned with maintaining secondary sex characteristics. At the time of puberty the controlling secretions from the anterior pituitary begin to appear and androgens are produced. There is a whole range of rare disorders, resulting in everything from precocious puberty to delayed puberty. It should be born in mind that the normal time of puberty can vary by several years from one boy to another.

Ovary. The human ovary has two functions: to produce ova, or eggs; and to produce two hormones, oestrogen and progesterone. These functions begin at puberty, one of whose features in the female is the onset of menstruation, or menarche. Just as in boys, the timing of normal puberty is very variable, but on the average, girls achieve puberty before boys. As social conditions improve, the age of menarche is getting younger generation by generation. All the secondary sex characteristics are under the control of the ovarian hormones which are released in response to the appropriate anterior pituitary hormones. The changes which occur in the womb and elsewhere in the intervals between menstrual periods and the periods themselves are controlled by a cyclical or rhythmic secretion, first of oestrogen and then of progesterone, by the ovary. This cycle is upset by pregnancy to allow the development of the embryo. It can also be upset by taking certain combinations of the two hormones by mouth. These can prevent the formation of ova, and are a popular form of contraception. In late middle age, the ovaries lose their function, the menstrual cycles cease to occur, and reproductive life is at an end. This is called the *menopause* or "change of life," and is sometimes accompanied for a time by distressing symptoms due to a temporary imbalance between oestrogen and progesterone. Many sexual functions, however, continue well after the menopause into old age, and these can include a continuing libido or sexual desire.

Parathyroid. Four tiny parathyroid glands are buried behind the thyroid gland and are responsible for regulating the body calcium and phosphate. They are therefore particularly important for the building and maintenance of bones and teeth. Since a proper calcium level in the blood is necessary for muscle (including heart muscle) contraction, and for correct functioning of nerves, disorders of the parathyroids can give rise to muscular spasms as well as loss of bone calcium. The latter can result in fragility and fractures. Overactivity of the glands leads to too much calcium and the formation of stones especially in the kidney.

Pineal. We end this section with a mystery gland. Like the pituitary it is small—about the size of a pea—and sits well back at the base of the brain. It was endowed in ancient times with metaphysical properties all of which remain speculative. In fish and lizards and certain lower vertebrates it is a kind of third eye, and receives light. In higher mammals, like ourselves, it is so far from any source of light that it could scarcely do so. It can be removed without harm. Indeed it normally becomes calcified and inactive about the time of puberty, and its position seen on X-rays of the skull can be a good guide to whether the brain is being pushed to one side by an abnormal mass.

DISEASES OF THE URINARY SYSTEM.

Everyone knows what kidneys look like—in fact, the term "kidney-shaped" is used to describe other objects. Within the kidneys the blood-vessels carrying waste materials subdivide and finally end up in little coils or glomeruli through which waste products are filtered into the other system, the system of tubes which, beginning as tiny cups around the glomeruli, become larger and larger until they join the ureter passing out at the root of the kidney, the hilum, a point at which both the veins and tubes enter and leave. The kidneys, of course, lie one on each side in the loins, so that if one puts one's hands on the hips and then slides them farther back they will cover the area over the left and right kidney. The ureters pass down on each side to the bladder, which is the storage tank of the products excreted by the kidneys, and lies in the mid-line down low in the abdomen; it is somewhat pear-shaped, and at its base in men there lies the prostate gland—a gland which apparently has few functions but can be a nuisance. Its only known function is that it adds something to the semen from the testes without which the semen would be sterile. Then, from the base of the bladder a single tube, the urethra, passes to the outside. One can, in fact, visualise the urinary system as a capital Y, in which the two upper limbs are the ureters, the place where they meet is the bladder, and the single limb at the foot is the urethra. Clearly, then, there may be diseases of the kidneys, of the ureters, of the bladder, of the prostate gland, or of the urethra.

The amount of urine may be increased or diminished. It is *increased* in the following conditions: after drinking excess of fluids; after taking drugs (known as *diuretics*) which are given to increase the flow; in diabetes of both types—mellitus and insipidus; in some types of chronic kidney disease; and finally, in emotional states of excitement. It is *decreased* in the following conditions: acute nephritis; any disease in which fluid is being lost in other ways, such as diarrhœa or sweating in fevers; when the fluid intake is small; and when both ureters are blocked by stones. Passing a great deal of urine is known as *polyuria*, passing very little as *oligouria*, passing frequent small amounts is simply called *frequency*. Normally, the urine is acid, but in infections of the bladder it may become alkaline owing to decomposition by bacteria. Abnormal substances, or normal substances in abnormal quantities, may occur in the urine and give the doctor an indication of what is wrong. In fact, urine analysis is a very important part of medical diagnosis. Thus urea is a normal content of urine which is increased in fevers, wasting diseases, or diabetes; the amount of urea is to some extent a measure of the degree of tissue breakdown. Uric acid is found in small quantities in normal urine, but the amount is increased in fevers and after an attack of gout (uric acid is important in the causation of gout, but has nothing at all to do with rheumatism in general, so one may disregard the advertisements in the popular Press showing unpleasant pictures of joints with sharp crystals of uric acid which are alleged to cause the pain of rheumatic disease). Oxalates are not ordinarily found in urine, but, since they occur in such foods as rhubarb and strawberries, and some people are unable to deal with them, such individuals may develop stones or have pain on passing urine after eating oxalate-containing fruits.

Two very important substances which ought not to be in normal urine are albumen and sugar. Albumen is a protein, and its presence in the urine indicates that the filters of the kidney are leaking—they are allowing protein to pass out which ought to remain in the body. Albumen is easily tested for, and its presence may indicate kidney disease or nephritis as it is usually called by doctors. On the other hand, small amounts of

albumen occur in fevers and in nervous conditions —*functional albuminuria*. Sugar, too, should not be present, but its presence does not necessarily indicate diabetes; for small amounts may occur in nervous conditions or in some people after taking large quantities of carbohydrate.

Blood in the urine may give it an appearance which varies from bright red to a dark, smoky colour. It is found in many diseases: acute nephritis, stone, tumours, poisoning by certain drugs, infections such as bilharzia or malaria, papilloma (*i.e.*, non-malignant tumour of the bladder), after injury, in high blood-pressure, scurvy, and blood diseases. Sometimes it occurs for no known reason at all.

It will be remembered (or if it is not, you can look it up on **P28 (1)**) that streptococcal infection of the throat may cause in some people disease of the valves in the heart or endocarditis. In such cases, although the germ is found in the throat, it is not found in the heart or indeed anywhere else in the body. *Acute nephritis* occurs in the same circumstances, with the sole difference that the kidneys instead of the heart are affected. The disease appears to be an allergic reaction to the toxins of the streptococcus. The patient, often a child, has a sore throat (and even this may be absent or fail to be noticed) or sometimes the infection may arise in other sites: after scarlet fever, erysipelas, burns, and disease of the ear. A few days later there is headache, vomiting, pain in the loins, slight rise in temperature, and especially typical is *dropsy* or œdema. This begins in the face, first around the eyelids, and then affects the ankles; later it may become more general and affect the rest of the body. Blood and albumen are found in the urine, and the blood-pressure is slightly raised. The outlook is usually good if the kidneys are rested by reducing the amount of protein taken in and also the amounts of salt and water. When this is done, the inflammation soon goes and no permanent harm results. In other cases, however, if treatment is inadequate or the condition severe, the symptoms may go, but the albumen found in the urine persists. This means that permanent damage has been done, and although there may be nothing else to show for many years, *chronic nephritis* develops. In this case, the blood-pressure continues to rise, and since the filters of the kidneys no longer work efficiently, urea, the principal waste-product of the body to be excreted in the urine, is retained in the blood and only small amounts escape from the system. Hence chronic nephritis sooner or later leads to heart failure or hæmorrhage in the brain from the rising blood-pressure, or to the form of poisoning known as *uræmia* which results from the retention of urea in the blood. Uræmia may come on suddenly or gradually, but ends in progressive coma, drowsiness, and unconsciousness. There may be convulsions similar to those of epilepsy, high fever, and difficulty in breathing to complicate the picture.

Another type of nephritis which seems to have nothing at all to do with streptococcal infections, and the cause of which is completely unknown, is *nephrosis*. Developing in early adult life, its onset is insidious, and the patient first shows signs of œdema in his white and puffy face and the swelling of his legs. (It should be said here that if you have swelling of the ankles or elsewhere, you would be foolish to jump to conclusions; for such swelling is common in many diseases—in heart disease, in allergic conditions, in neurotic illness, and even just from hot weather.) When the urine is examined in a case of nephrosis it is found to be full of albumen and, as in chronic nephritis, the blood urea starts to rise. The end-results of nephrosis are the same as those of chronic nephritis and depend upon the damage originally done.

The modern diuretics of the chlorothiazide group help to control the œdema and, provided enough healthy tissue remains, remove both the fluid and the waste-products. In advanced or more serious cases artificial kidneys can be used, but as yet the transplantation of a kidney is largely in the experimental stage.

Pyelitis is an infection of the pelvis of the kidney, that is to say, of the part where the ureter leaves the kidney. It is usually caused by the bacillus coli, which is normally present in the body, or by the streptococcus. These germs may reach the ureter through the blood-stream or may pass upwards from the bladder. Obstruction anywhere in the urinary tract which causes the urine to stagnate is liable to cause pyelitis. Symptoms come on suddenly, with high fever, pain in the loin (the infection is usually on one side only, and is commoner in women), and pain in the abdomen. When urine is passed there is a burning sensation, and it is passed frequently and in small amounts. On examination, the urine is found to be highly acid and full of bacillus coli or whatever the causative germ may be. Pyelitis is fairly readily treated by the antibiotics or sulpha drugs. Plenty of fluids should be given and the urine made alkaline by administration of alkalis.

Cystitis means inflammation of the bladder, either acute or chronic, and its causes are much the same as in the case of pyelitis. There is pain over the lower abdomen, frequency, and sometimes slight fever. The treatment is as for pyelitis. *Urethritis* is an inflammation of the urethra, with burning pain on passing water and frequency. The most serious cause (although it can usually be easily dealt with now) is gonorrhœa. But non-specific urethritis is common, and in this case various germs or none may bring about pain and frequency; there is often a large neurotic element. Urethritis should be regarded as probably due to gonorrhœa, which has already been discussed elsewhere, when there is a thick, creamy discharge from the penis or discharge in women following sexual intercourse with an infected person.

Kidney stones or Renal calculi sometimes form, and, as in the case of gall-stones, what causes them is not certain. They may be caused by disorders of metabolism—that is, in the inability of the body to deal with calcium, proteins, uric acid, and other products; or by vitamin deficiency, obstruction in the urinary tract, and urinary infections. But when a stone or stones are formed various events may occur: thus it may remain in the kidney and cause no symptoms; or it may cause repeated attacks of pain, infection, and blood in the urine (hæmaturia); or it may completely block the passage of urine from the kidney to such a degree that it degenerates and becomes useless; or, lastly, it may pass into the ureter, and when this occurs very severe pain, known as *renal colic*, will occur. A stone passing down the ureter into the bladder may become stuck in the urethra, although this is uncommon, since a stone small enough to get down the ureters is likely to be capable of manœuvring through the rest of the tract. In fact, about 80–90 per cent. of stones are passed spontaneously. Stones not passed spontaneously may have to be removed by operation, but whether this is undertaken or not depends on various factors, such as the general health of the patient, the amount of trouble caused by the stone, and the health of the other kidney —for it is dangerous to operate on one kidney unless one is sure that the other is functioning efficiently.

If a stone blocks the passage of urine on one side for any length of time *hydronephrosis* may result, in which the part where the ureter enters the kidney swells with the retained urine. Ultimately much of the kidney may be destroyed by the back-pressure. The same effect may be produced by kinking of the ureter or anything else which causes obstruction. Sometimes children are born with hydronephrosis, and when the dilation is due to kinking of the tube the condition may be intermittent, with attacks of renal colic during which only small amounts of urine are passed; this is followed with relief and the passage of large quantities.

Tumours and Cysts. The kidney may also be the site of tumours and cysts which produce pain in the loins, sometimes a lump over the kidney which can be felt, and blood in the urine. Cancer of the bladder is a serious condition in which the bladder may have to be removed, so the urinary flow has then to be directed elsewhere. Either the ureters are brought out on to the skin surface, a procedure known as *cutaneous ureterostomy*, or they are implanted in the large bowel, so that the urine flows out with the fæces. This is described as *uretero-colostomy*.

There may also be benign tumours of the bladder or *papillomas*, which are soft and bleed easily; a great deal of blood is passed, but there is usually little or no pain. In this, and similar, diseases of the bladder examination of the inside of the organ is carried out by means of a cystoscope, a thin tube which is passed up the urethra and has a small electric light at the end which enables the surgeon to see what is going on. Instruments may also be passed through the tube, and simple papillomas can be cauterised. Similar instruments are used in the examination of the stomach (gastroscope) and the bronchial tubes (bronchoscope). When some obstruction in the outlet of the bladder or in the urethra occurs the bladder, of course, fills with urine, which cannot be passed, and very painful dilation occurs. In this case an attempt may be made to pass a catheter, a thin rubber tube, into the bladder to relieve the tension, or if this fails a *suprapubic cystomy* is performed—an incision is made in the abdomen over the bladder and a tube inserted into it, through which the urine escapes. This is ordinarily a temporary expedient, and later when the patient's health has improved an attempt will be made to remove the cause of obstruction. The most common cause of such obstruction is *enlargement of the prostate gland* at the base of the bladder, which surrounds this area and the beginning of the ureter. About 40 per cent. of men over sixty have some degree of obstruction due to this cause, and about 20 per cent. of these require operation. The gland is about the size of a walnut, and, as we have seen, its function is to supply part of the fluid which makes up the semen, the male sex secretion. Enlargement of the prostate may be benign or malignant, and, although nobody knows just why, such benign enlargement tends to occur in most men in later life. There may be no symptoms, but characteristically there is frequency during the day and the need to get up at night to pass water. The flow of urine being impeded by constriction of the urethra, the passage is less forceful than normal, and there is a tendency for dribbling to occur. If the obstruction is severe and not relieved the back-pressure may be transmitted to the ureters and kidneys, resulting finally in kidney failure and uræmia. The prostate, except in cases of very mild enlargement, has to be removed either through the abdomen or through the perineum (the part of the body lying between the sex organs and the anus). Sometimes, in less serious cases, it is possible without an incision to cut away the obstructing part by an electrocautery inserted, as is a cystoscope, through the urethra. Prostatectomy was once a serious operation, all the more so because the patient was usually elderly and not in good condition, but new techniques and the use of antibiotics have greatly improved the outlook.

Cancer of the Prostate is always serious, but if discovered in time it can be operated on successfully. The gland, of course, has to be completely removed; in inoperable cases, or in patients unfit to stand operation, the tumour may be treated by means of female sex hormones, which cause it to shrink and may prolong life by some years.

DISEASES OF THE NERVOUS SYSTEM.

The nervous system consists of the Central Nervous System and the Peripheral Nervous System. The brain and spinal cord make up the former. The latter consists of the nerve fibres by which the Central Nervous System is connected to all parts of the body. Human beings have a more complicated brain than any other animal species, but it is only its complexity which makes it different from the brains of other mammals like rats and pigs and cows. We do not have the largest brains, since whales, for example, have much larger ones. Ours is not even the largest for the size of the body. Mice and dolphins and several other creatures have relatively larger brains when compared with body weight. Furthermore the cells and materials of which our brain is composed are virtually identical with those in other mammals, and its living properties are also the same.

Before describing some of the diseases of the nervous system it will be helpful to say a little about how it is made and how it works. Each human brain probably contains about ten thousand million (10,000,000,000) nerve cells and perhaps four or five times this number of supporting "glial" cells. Each nerve cell has many long thin branching projections, called dendrites, rather like the branches of a tree, leading to many thousands of "twigs" for each single nerve cell. At the end of each "twig" there is a special structure called a *synapse* by which contact is made with other nerve cells. It is through these connections that very large numbers of nerve cells give information (or send impulses) to each other so that they can be co-ordinated. As well as these dendritic branches, each nerve cell gives off one large trunk called the *axon*, down which final messages are sent as the result of all the information it receives from its dendrites. Some axons are many feet long. Some end in another synapse, by which the outgoing message is passed to yet another nerve cell. Some axons, those of the peripheral nerves, end directly on organs like muscles or glands, instructing them and making them work.

Messages are passed along dendrites and axons as electrical impulses. These are generated in the nerve cell "body." They are modified according to information received from other nerve cells and propagated down the axon. It is this superficial resemblance to a series of electrical cables which has given rise to comparisons of the brain with a telephone system or a computer, and as long as it is realised how infinitely more complicated each brain is than any known computer, the comparison is not a bad one. However, the brain generates its own electric power from the fuel brought in its own blood supply; and no spare parts or spare cables are available if the originals should get damaged, except in peripheral nerves. Furthermore the contact of one nerve cell with another through a synapse is not an electrical contact, and neither is the contact between a nerve and the muscle or other organ it is controlling. In both cases the connection is chemical. Thus when an electrical impulse arrives at the end of the nerve fibre, a chemical is released into the gap between it and the next nerve or organ, and it is this chemical which carries the stimulus forward. There is also an arrangement to neutralise the chemical transmitter when the impulse has been transmitted. So the resemblance to a telephone exchange or computer can sometimes be misleading.

Many of the nerve axons which transmit electrical impulses are clothed in fatty *myelin sheaths*, a little like the plastic insulation around an electric wire. Here again the resemblance is only partial, since the myelin sheaths are interrupted at regular intervals and these gaps in the insulation play an important role in transmitting the impulse. One of the important functions of the non-nervous *glial* cells of the brain is to manufacture and maintain the myelin sheaths.

Most of the functions of the brain are quite unknown, and even the ones we know about are very poorly understood. It is assumed to be the organ of higher mental function, of the mind and intellect; but there is surprisingly little evidence for this, and no one has any idea what physical structures or mechanisms subserve these functions. The brain is known to control all bodily functions by means of *motor* and other nerves which carry impulses from the brain outwards to all parts of the body. Sometimes these are under our voluntary control; mostly they are involuntary, reflex or automatic. Reflex actions are the result of impulses passed inwards from the body towards the brain by means of sensory nerves. Information arriving in the brain about the various sensations like heat, pain, touch, position, the need for saliva or gastric juice or even the thought or smell of food, are acted on in the various "centres" in the brain. These send out instructions down the "motor" or "secretary" nerves which instruct the muscles or glands to take appropriate action. Thus a *reflex* has a "sensory ending" which appreciates some sort of sensation. This is converted into an electrical impulse which is sent towards the brain or spinal cord along a sensory or "afferent" nerve. The impulse arrives at a "centre" in the central nervous system which co-ordinates all the relevant information and issues instructions. These travel

as impulses outwards, along "efferent" nerves towards "effector" organs like muscles or glands, and an appropriate action occurs automatically. The pathway from sensory ending to effector organ is called a *reflex arc*. Many reflex activities are partly under voluntary control, although mainly automatic. If you touch something hot you will automatically withdraw your hand. But if it is a hot china cup which has cost you a lot of money, you are capable of overriding the tendency to drop it, at least for a time. Breathing is automatic, but it can also be controlled, again at least for a time.

Clearly the brain is a very delicately organised piece of machinery, and its cells are extremely specialised for their job. Achieving this kind of specialised perfection brings many difficulties, however, and the brain cells have become highly dependent on the proper functioning of the other body systems, especially the blood circulation, the respiratory system, and the systems regulating the detailed nutrient composition of the blood. Failure of these systems, even for a very short time, can damage the nerve cells. Nearly all death, from whatever original cause, is produced this way, by an ultimate interference with nerve cell function.

We have already mentioned that the brain and spinal cord are unable to repair or replace any components which get damaged. The vulnerability of the brain is even more obvious when it is realised how easily damage and destruction can occur. For example, unless a rich supply of oxygen and glucose is continuously arriving in the blood stream, brain cells will cease to function in a few seconds and will die in a few minutes, and they can never be replaced. This is in marked contrast to other tissues of the body. The leg, for example, may carry on for over half an hour without any blood at all because the muscle and other cells can find other ways of surviving. Thus the brain can be permanently damaged if the blood contains insufficient oxygen (through asphyxia), insufficient glucose, or if the blood supply is blocked or if the blood pressure falls. All these are likely to happen to any of us at any time, and so there are elaborate mechanisms trying to prevent them occurring. Most of the subject of physiology is concerned with the mechanisms designed to protect the brain, and most of us ultimately die because they eventually fail. One of the clever features of the body design is that all the mechanisms which protect the brain from a supply failure are controlled by the brain itself. Thus the brain has itself been made to control the heart beat and the breathing and the many other systems which are needed for its own survival.

In all that follows concerning disease of the nervous system it will be seen that the effects of neurological disease on the patient are the direct result of something going wrong with one of the structures or mechanisms we have described.

Diagnostic Techniques in Neurology. The doctor has many ways of testing the nervous system, most of which test its various functions as outlined in the introduction. Thus tests of sensation, muscular movement and reflexes of all kinds as well as the special functions of taste, smell, vision, hearing, speech and intellect play a part. *X-rays* only show the skull because it is calcified, the brain not being seen directly. There is, however, a tiny pea-size central structure called the pineal gland which usually becomes calcified with age, and this shows up. If for any reason the brain is pushed over to one side of the skull this can be detected by displacement of the pineal. A great deal can be learned about the brain by *arteriography*. In this test a radio-opaque substance is put into the arteries supplying the brain, and an X-ray picture taken immediately afterwards shows up all the blood vessels. *Ventriculography* is an X-ray examination after gas has been introduced into the brain cavities or ventricles which are normally filled with *cerebro-spinal fluid*; *myelography* is an X-ray of the spinal cord after a radio-opaque substance has been injected into the space between the spinal cord and the bony vertebral canal which houses it. All these X-ray procedures are ways of looking for a change in the shape of the brain or its vessels. Sometimes *radioactive isotopes* are put into the blood stream and carried into the brain where they can be detected from outside the skull by counters. *Electroencephalography* measures the electrical waves generated by the brain by placing electrodes on the scalp. *Electromyography* does the same for muscles.

Consciousness and Unconsciousness (*Coma*). Everyone knows what consciousness is until he tries to define it. Full consciousness is generally taken to imply not only wakefulness but the total complement of human mental faculties. In clinical medicine, however, something less than this is usually meant. For example a demented person, or one whose memory is lost (*amnesia*), or one whose powers of speech are lost (*aphasia*) may still be "conscious." There is really a continuous gradation between full consciousness and coma, passing through drowsiness and even "stupor" in which condition a patient can be aroused from coma but sinks back into it when left alone. Many different things can cause coma ranging from swelling of the brain, compressing it in its rigid box of bone, to disorders in other body systems resulting in a failure to provide for the brain's needs. Examples of the first are bleeding within the brain or *brain tumours*, both of which occupy space and can only do so by producing compression. In the second category are asphyxia preventing oxygen from reaching the brain, lack of glucose in the blood, circulatory failure in which there is insufficient blood, or insufficient blood pressure. Fainting is a comparatively minor example.

Sleep and Insomnia. Nobody knows what causes sleep, why it is necessary, and how it helps. It is quite different from coma or even stupor, since as much oxygen and glucose is necessary asleep as awake. Insomnia is experienced by everyone at some time, and for some reason is very distressing if it persists. There are three forms: failing to get to sleep, intermittent wakefulness, and awaking early. Nearly all insomniacs sleep more than they think. They should eat light evening meals and avoid stimulants like tea and coffee after mid-day. Elderly people should realise they need less sleep. Being cold or having a full bladder can be a cause. Or simply not being tired. Sedative drugs are a last resort, but they can be useful in "breaking the habit" of wakefulness. Obviously there may be psychological factors such as anxiety and excitement. *Narcolepsy*, or a true inability to keep awake is comparatively rare. Both narcolepsy and insomnia are really extreme examples of what all normal people suffer from occasionally.

Headache is man's most common pain. Here again we must distinguish between the very common varieties of comparatively trivial significance and the rare ones due to serious causes. Some headaches are due to continuous tightness in muscles of the scalp, and are often "nervous" or psychological in origin. Others result from nose blockage and congestion, sinus problems, eye strain, toothache, etc. Migraine is a special kind and will be described below. Very occasionally indeed headache is due to serious disease like brain tumour. Most headache results from "living it up" or being "run down," or both. The headache of alcoholic hangover is probably due to dehydration. It can often be avoided by consuming a great quantity of water (a pint or two) before going to bed, but few people are prepared to do this in the circumstances. Be careful when using aspirin, which is a useful remedy for headache, since it is very dangerous for people with stomach complaints like gastritis or gastric or duodenal ulcer. Occasionally aspirin makes the stomach bleed, and this can be so severe as to kill. A safer pain killer is paracetamol. Be particularly careful in treating "hang-over" headaches by patent fizzy remedies. They are very effective, but often contain large quantities of aspirin described in small print by its proper name as acetyl salicylic acid.

Migraine. This is a very special variety of "sick headache" and requires special treatment under medical supervision. It has many different forms, but usually there is a definite sequence of

events. An attack often starts with some alteration of vision. The patient has shimmering blind spots or other visual disorders. This is followed by a well localised severe headache which may end in nausea or vomiting. The whole thing is caused by a poorly understood disorder of the blood vessels. There are special drugs, mostly derivatives of ergot, which are effective, especially if used when the first signs of an attack appear. Although there is a direct physical cause for an attack, it is also certain that some of the trouble is psychological tenseness. People with migraine are often rather anxious, striving and perfectionist people. Also it has been noticed that attacks are much less frequent when the necessary pills are being carried available for use. However, as with all other conditions which are partly "psychological" in origin they are none the less distressing for the patient. It simply means that the treatment is also partly psychological in encouraging him to come to terms with his problems.

Menière's Disease is one of the conditions in which the organ of balance in the middle ear is affected, giving rise to *vertigo*, a form of giddiness. It usually begins in middle life in the same sort of person who sometimes has migraine. There is buzzing in the ears and some intermittent loss of hearing as well as vertigo. During an attack the patient may be unable to walk because of his loss of balance, and nausea and vomiting are common. Treatment is by special drugs, and occasionally an operation on the ear is necessary.

Epilepsy is a symptom, not a disease, which is common at all ages but especially children. It has been attributed to St. Paul, Julius Caesar, Napoleon, and (with more justice perhaps) to Dostoyevsky. Many varieties of attack occur often in the same patient, the commonest and best known being the *grand mal* or major seizure. In this the patient falls down unconscious and rigid and the jaw is clenched, so that there is danger of the tongue being bitten. This so-called tonic phase is followed, within a minute or so, by a clonic phase in which the limbs contract rhythmically. The attack ends with the patient going limp and gradually recovering consciousness, a process which may take up to an hour. Occasionally the patient has a brief warning, most often an indescribable feeling in the stomach. There are two common forms of minor seizure, one occurring mainly in children and the other more often in adults. The common minor attacks in children are often called *petit mal* or *absence*, which well describes the instantaneous and brief loss of consciousness often unaccompanied by any change in posture. Recovery is equally instantaneous. On the other hand, in the other forms of epilepsy which arise from various parts of the brain, but especially from the lobe under the temporal region, there is often a warning similar to that which may precede a major seizure. In these cases the patient shows only confusion, no definite loss of posture, but automatic activity such as fumbling with buttons, muttering, and grimacing. Following these attacks there may be a quite prolonged period of confusion in which the patient may wander away and occasionally may be violent. Criminal acts are very rarely carried out in this state.

A large number of people have had one or two fits in their lives, particularly at times of physical or psychological stress. "Fever" or "Febrile" convulsions (often called teething fits in the past) are extremely common in young children and are often thought of as something different from epilepsy since the attacks rarely continue in later years. This form of epilepsy and some cases of *petit mal* are the only forms in which hereditary factors are important in the causation, and these are the least serious forms of epilepsy. They are very rarely associated with serious physical or psychological disturbances. Most other forms of epilepsy are due to a scar or other area of brain damage. It is a proportion of these cases which develop the psychological disturbances that are occasionally very serious.

Not every patient who has had one or two fits need necessarily take regular anticonvulsant drugs; that is drugs which damp down the abnormal excessive activity of the brain that leads to the attacks. Many drugs are available of which the most important are phenobarbitone, phenytoin, succinimides, and troxidones, the last two being effective only against minor seizures. Which one to use and whether to use one at all is, of course, quite a complicated judgment, and must be left to the doctor. Epileptics often find it difficult to get work because of the reluctance of employers to take on someone who may be more prone to accidents and whose fits may distress other workers. Obviously there are some jobs which epileptics should not do because of the danger involved (from, for example, moving machinery), and they should not drive a car. A few cases are so severe that work is almost impossible, but employers have a duty whenever possible to employ these people whose mental health may suffer greatly if they are made to feel outcasts and who ordinarily are as efficient, or even more so, as the next man. It is also hoped that employees will become less prejudiced about epilepsy as the general public become less ignorant about medical matters. In this way epileptics will come to be accepted in all those kinds of employment for which they are well suited. If some of the famous men who have suffered from this disease had had to rely on the charity of some employers today the world would have been much the poorer, although possibly we could have managed without the generals.

Congenital Malformations. The proper shape of the brain and spinal cord is achieved quite early in development by about the thirteenth week after conception. During this time very slight changes in the fetal environment can produce disastrous malformations. The drug thalidomide, for example, operated on other body systems while they were passing through this phase of construction. Some viruses can do the same thing. Most malformations are without known cause, but it is certain that something went wrong at this very early stage, and it only needs a very minor interference with the normal process to do the permanent damage. At about this time the bones of the spine are beginning to enclose, or form a roof over the developing spinal cord. Sometimes they fail to complete the process, resulting in *spina bifida*. If the coverings of the cord protrude through the defect, this is a *meningocele*, and if the cord itself protrudes it is a *meningomyelocele*. The whole protrusion may be covered with skin, but if it is not, the cord soon becomes infected. The effect on the patient is variable, according to the amount of damage to the nerve fibres in the cord, and there are varying degrees of paralysis and loss of sensation below the area involved together with loss of bowel and bladder control. Much help is often obtained from surgical repair, but many cases remain in a distressing condition always, and the only really useful attack on the problem is research to find the cause and prevent it happening. The same is true of the *malformations of the brain*. In one of these, hydrocephaly, the narrow channel is blocked which transmits the cerebrospinal fluid from the chambers within the brain where it is secreted to the outer coverings to be taken back into the blood stream. Blockage of the channel (or aqueduct) results in distension of the brain by fluid, enlargement of the head, and mental retardation. Sometimes a by-pass valve can be inserted to restore normal fluid circulation with very gratifying results. This aqueduct can also be blocked by later disease (meningitis) or injury with the same result. Sometimes the brain fails to form altogether (*anencephaly*), and the child fortunately does not survive after birth.

Cerebral Palsy is a term covering many varieties of *spastic child*. It is thought to be due to brain damage at birth or in early infancy, and is depressingly common. Although a great deal can be done for the spastic (they are often of normal intelligence) the only satisfactory approach is prevention and this means expensive research into its causes. Donations, encouragement, and offers of practical help, please, to the Spastics Society 12 Park Crescent, London W.1.

Motor Neuron Disease. This is a group of distressing diseases usually occurring in people over 40, in whom the parts of the brain and spinal cord degenerate which look after muscular movement. The group includes *Amyotrophic Lateral*

Sclerosis, Progressive Muscular Atrophy, Progressive Bulbar Palsy, and *Primary Lateral Sclerosis.* The results are paralysis or weakness with wasting of the muscles of the body, including those concerned with arms, legs, breathing, speaking, etc. Nothing whatever is known of the cause, and the only treatment is that designed to alleviate the results of the disease. It is uncommon, but this is little comfort to the sufferer.

Parkinson's Disease, paralysis agitans, or the "shaking palsy" is a common condition which begins in later life over the age of 50. It has three classical features: shaking (or tremor), muscular rigidity and loss of those automatic reflexes which look after bodily posture. This results in a stooping shuffling gait. Later there is a mask-like loss of facial expression with diminished eye blinking. It is a progressive disease, but it progresses so slowly that 10 or 20 years may elapse between its onset and incapacity. A good deal can now be done to help these patients with drugs, the most recent of which at the time of writing is DOPA. Occasionally patients have benefited from surgical destruction of small areas of diseased brain. It is important to remember that many elderly people have some tremor of the head or hands called *Senile Tremor,* and this is *not* Parkinson's Disease. It is merely one of the features of achieving advanced seniority as a citizen. *See also* P62.

Chorea. This is a group of diseases in which there is involuntary muscle movement, weakness, and emotional instability. There will be clumsiness, awkward gait, twitching of limbs, face, hands, trunk, or tongue. They include *Acute Chorea or St. Vitus' Dance* occurring in children from 5 to 15, *Hereditary or Huntingdon's Chorea* occurring in a well-defined genetic pattern and beginning later, between 35 and 50. *Tics* or habit spasms are not part of these diseases but are often of psychological origin. They are usually eye blinking, head shaking, shoulder shrugging, or any other sudden gesture of limbs or face.

Stroke Illness or Cerebrovascular Diseases. Strokes are due to diseases of the brain's blood vessels which either burst or get blocked. The same blood-vessel disorders cause heart attacks by blocking the coronary arteries supplying the heart. Strokes and heart attacks together kill more people than any other single cause including cancer. They account for one death in every five. Perhaps less is known of the cause of this disease than is known about cancer, and much more research is needed to find out if it is to be prevented. The cause of the commonest cancer (of the lung) is now known and it can be prevented by stopping smoking. Perhaps the prevention of strokes and heart attacks will mean an equally difficult abstinence from all those foods which make us fat. At least it is known that being overweight leads to death from these causes, just as smoking leads to death from lung cancer.

If any artery supplying blood to any part of the brain is blocked, the territory supplied will die; and the bodily functions for which that part of the brain is responsible will cease. The process is called *infarction* of the brain, the dead area being an *infarct.* The blockage is usually due to thrombosis (*see* P31) of the blood within a vessel, a *thrombus* being a rather complicated clot with a structure of its own. The underlying cause is the arterial disease, atheroma (*see* P30) together with stagnation of the circulation. About one blockage in ten is due to a small piece of a much larger thrombus in the heart chambers being flung into the blood stream and impacting in the distant vessel in the brain. This is *cerebral embolism* (*see* P30). If the area of dead or infarcted brain is not too large the patient will recover from his unconsciousness, but will be left with permanent loss of function (paralysis, etc.) related to that part of the brain.

When a blood vessel supplying the brain bursts, this causes *cerebral haemorrhage* or apoplexy. The vessel may be on the surface (*subarachnoid haemorrhage*) or in the depths of the tissue (*intracerebral haemorrhage*). Strokes tend to occur in older people, because the associated arterial disease is a product of age and high blood pressure. Occasionally a subarachnoid haemorrhage occurs in a younger person with an unsuspected malformation of the arteries of the base of the brain known as a *berry aneurysm.* This is a small berry-sized blown-out balloon due to a defect in the wall of the vessel. Berry aneurysms can often be treated surgically. Intracerebral haemorrhage carries a very poor outlook, however, since much brain tissue is often destroyed by the escaping blood, especially the deep tissues responsible for the vital functions. Haemorrhage within the brain cavity can also be caused by injury (*see concussion and compression,* P19).

Inflammatory Diseases of the Nervous System. The membranes covering the brain are called the meninges. Inflammation of these, nearly always by blood-born infection or infection following injury, is called *meningitis.* Cerebrospinal or spotted fever which used to be common and very much feared was only one variety caused by a germ called "meningococcus." It is now rare. Almost any other germ may cause meningitis, and when the germ is susceptible to one of the antibiotics it is usually treatable. It will usually be necessary to identify the germ by taking a sample of cerebrospinal fluid from a convenient space around the spinal cord in the lower back. When the disease is caused by the tubercle bacillus (*tuberculous meningitis*) the problem is more difficult because the patient is often not so obviously ill until the later, less treatable stages. *Cerebral abscess,* or abscess of the brain is very serious because it occupies space in the closed box of the skull and compresses the brain, as well as being a destructive process. It may arise due to an infected piece of tissue or pus being carried to the brain in the blood stream from a distant site in the lungs or heart. When the brain or cord tissue is itself inflamed it is called *encephalitis* (brain) or *myelitis* (cord) or *encephalo-myelitis* (both). These conditions are comparatively uncommon and are often due to infection with viruses rather than bacteria. Some have no known cause, possibly because many viruses are difficult to identify.

Multiple Sclerosis or *Disseminated Sclerosis* or the "creeping paralysis" as it used to be called, is the most important of the "*Demyelinating diseases,*" in which the myelin sheaths wrapped around the nerve fibres disintegrate. This only occurs in small areas, or plaques. It is as if drops of acid have been placed at random throughout the brain and spinal cord and have dissolved away the insulating sheaths over sixpenny (or new penny) sized areas, leaving the wiring (the nerve fibres) running through as before. But this small loss of insulation is enough to spoil the carefully graded electrical impulses; and thus the bodily function subserved by those fibres is lost. So there are apparently random losses of sensation, movement, bowel or bladder control, speech, etc., according to which collection of nerve sheaths happen to have been attacked. Thus it is that no two cases are alike and many are difficult to diagnose. Many have even been labelled malingerers in the early stages, so bizarre are the signs and symptoms. The disease is not a killer. It smoulders on year after year, often beginning in the late teenager and getting steadily more incapacitating over many decades. No one can predict how quickly it will deteriorate, and in some cases many years will go by before yet another episode of more myelin sheath destruction. Neurology has more than its share of completely mysterious diseases. This is perhaps the most mysterious, and it is not very uncommon. The many years of disability in each individual case make it at least as disabling as far commoner diseases which run a much shorter course. There is no more enhumbling disease for the medical scientist, but the faith must remain that, with more and more research, this crippling condition too can be prevented. The Multiple Sclerosis Society, 4 Tachbrook St., London S.W.1, looks after patient welfare, supports research and is very deserving of your donations. As in all other crippling conditions there are countless ways in which you can help the victims at no great expense. Visit them. Help with their shopping and other day-to-day needs. Take them out. And even write to your member of parliament demanding a better deal for the disabled who are

still, in spite of recent legislation, among the most downtrodden and deserving of our neighbours.

Myelin sheaths are largely made of fats, so it is small wonder that the brain has its full share of complicated biochemical mechanisms for dealing with fat and manufacturing it. Hand in hand with this is a host of comparatively rare diseases, known as the *lipidoses*, which are basically disorders of fat biochemistry. Among the best known are *Tay-Sachs disease*, *Niemann-Pick disease*, *Gaucher's disease*, and *Hurler's disease*, and it is beyond the scope of *Pears* to describe them in detail.

Brain Tumours. The brain is no exception to the rule that any cell in any tissue of the body can suddenly begin to disobey the body's rules regarding its growth and multiplication. A totally unknown mechanism governs how many cells of a certain type there ought to be and calls a halt to cell multiplication when this number is reached. Every now and then one of them turns a blind eye and goes on dividing, and the result is a tumour, or lump, of anarchic cells which obey no rules. Tumours are commonest in cells which normally go on dividing throughout life, in order to replace those lost by wear and tear. Examples are the cells lining the air passages in the lung, or the alimentary tract in the stomach or large bowel. Fortunately for the brain there is little cell division once it has grown. Nerve cells cannot divide at all in adult life, and the supporting glial cells only do so in response to injury. Therefore primary brain tumours are much less common than those elsewhere. Also many brain tumours like many of those elsewhere, are benign or "innocent" tumours. They are not cancerous, and need only be removed for the patient to be completely cured. The brain, however, is at two major disadvantages compared with other tissues when it comes to tumours. One is that all tumours as they grow take up space, and space in the skull is already fully occupied. Thus even an innocent tumour can compress the brain within its rigid box of bone and become most dangerous until it is removed. The second disadvantage is due to the very large blood supply of the brain. Cancer in other parts of the body spreads partly by sending small pieces of itself to other tissues by way of the blood stream, and those tissues like liver, lung, kidney, and brain which have a big blood supply naturally receive more than their share of other tissues' tumour. These secondary deposits, or *metastases*, cause compression and other trouble in the brain much more frequently than the brain's own primary tumours. Indeed convulsions or other signs of brain disorder may be the first indication that there is a primary tumour in the lung or breast or elsewhere.

Head Injuries are dealt with in the section on Physical Injuries (P19), where a great deal of space is given to the effects of most First Aid emergencies on the proper functioning of the brain and spinal cord.

Diseases of Peripheral Nerves. Compared with the nerves of the central nervous system (brain and spinal cord), the peripheral nerves are comparatively rarely affected by disease. They have some similarities of structure with central nerve fibres in that their fibres are often covered with myelin sheaths and are arranged in bundles. A special feature, however, is that they are enclosed by connective tissue sheaths and it is probably these which allow a peripheral nerve to grow again, or regenerate, after it has been cut or damaged. Central nerve fibres are unable to do this. After *injury of a peripheral nerve* the part away from the centre is cut off from its parent cell body and it dies. All function, whether motor or sensory, is lost. But in the course of many months the central surviving part grows into the connective tissue sheaths which act like tubes to guide the new nerve to its destination. Provided the cut ends are close enough together and correctly aligned, and provided enough fibres reach their correct destination, good functional recovery is possible.

A disorder of a peripheral nerve is called a *neuropathy* and means nothing more than that. There are many kinds. One of the most distressing is *trigeminal neuralgia*, again fortunately rare. The trigeminal or fifth cranial nerve has a motor and sensory territory on the face. In this condition there are paroxysmal episodes of extremely severe pain which may resist all treatment except destruction of the nerve itself with consequent facial paralysis and loss of sensation. At the other more trivial extreme are the occasions when a leg "goes to sleep" or gets "pins and needles" after crossing it and pressing on a nerve for too long. *Bell's Palsy* is sudden loss of function of the seventh cranial nerve and there is again paralysis on one side of the face which usually recovers in time. Some bacterial diseases, especially leprosy, invade the nerves themselves. Chronic alcoholism may affect the nerves, as may diabetes, probably by interfering with the nutrition of the nerve cell. So may exposure to arsenic or lead or an unpleasant nerve poison which may contaminate cooking oil known as TOCP, or triorthocresylphosphate.

Muscular Dystrophies. These are a series of diseases of muscle in which there is progressive wasting and weakness of muscle, the causes of which are entirely unknown. They are divided up according to the age of onset and the muscles involved. *Duchenne's muscular dystrophy* occurs in the first decade of life. It affects most of the muscles eventually, including the heart muscle and those concerned with breathing, and so the outlook is not good. Other forms are inherited.

Myasthemia Gravis. This is a strange disorder of the mechanism which transmits instructions from nerve to muscle at the "neuromuscular junction." There is extreme weakness of muscles after they have been used, resembling in some respects the weakness following the administration of curare, or "arrow poison." It is often associated with disorders of the thymus gland. The drug neostigmine reverses the neuromuscular disorder and removal of the thymus is also sometimes effective.

MENTAL DISEASES.

Psychosis.

Mental diseases are divided into psychoses (*i.e.*, insanity) and neuroses (*i.e.*, what is ordinarily known as "nerves"). Psychoses, in their turn, are divided into organic and functional—those due to physical disease and those in which no physical cause has been discovered. In point of fact, the distinction into organic and functional is rather meaningless; for if we accept the modern view of psychosomatic medicine which regards the body and mind as a single unit it is clear that organic disease brings out psychological defects which were already there and that functional disease must, in the final analysis, be the result of physico-chemical causes, even if this is brought about by mental stress.

Organic disease results from poisoning of the nervous system by such poisons as alcohol, carbon monoxide, or lead; vitamin deficiencies, as in pellagra; infections such as syphilis; and degeneration of the brain, either primary or as a result of poor blood supply. In all cases its main symptoms are confusion, signs of other disease, and loss of memory. Alcohol leads to various conditions: in *delirium tremens* heavy bouts of drinking end in delirium ("D.T.s"), confusion, hallucination—although not necessarily of pink elephants or rats. It is a serious disease, but the outlook is much improved since it was discovered that injections of concentrated vitamins B and C in the form of "Parentrovite" can help. In more chronic cases *Korsakov's syndrome* manifests itself in the form of mental deterioration and memory defects. There can be little doubt that previously existing mental instability is a predisposing factor in these conditions. The same may be said of *general paralysis of the insane* or G.P.I., and in this case the immediate cause is syphilitic infection of the nervous system. Nevertheless, of all the patients with chronic syphilis, only a small number get syphilis of the nervous system. G.P.I. is typically associated with the usual symptoms of organic disease and delusions

of grandeur; for example, a man with this disease may go out and buy several expensive cars in one day. However, it is not uncommon to find G.P.I. associated with severe depression—again the picture depends on the previous personality. The association of the above symptoms with a positive Wasserman test—which proves the presence of the spirochæte in the blood—indicates neurosyphilis. When the lower centres of the nervous system are affected the disease is known as *tabes dorsalis*, in which there is difficulty in passing urine, limb pains, inability to stand when the eyes are closed, and finally difficulty in walking. The patient becomes paralysed and ultimately bedridden. Treatment is with penicillin.

People age at varying rates, so that some are hale and hearty at eighty or ninety whereas others are old at sixty or seventy. They present the typical picture of old age: "second childishness and mere oblivion, sans eyes, sans teeth, sans everything." When this condition, which is caused by degenerative changes in the brain or by defective blood-supply resulting from arteriosclerosis, is pronounced we speak of *senile psychosis*. There is mental confusion, forgetfulness, and delusions, in which the previous personality defects which we all have are accentuated. Such patients may have to be put under special care, but the process is largely irreversible.

The functional psychoses are two in number: schizophrenia and manic-depressive insanity. In *schizophrenia*, which, when it occurs in early adult life, is known (or used to be known) as *dementia præcox*, the symptoms are bizarre. There are delusions and hallucinations, so that the patient often believes himself to be persecuted and hears voices which say objectionable things to him. Sometimes the schizophrenic is wildly excited, and in other cases he goes into a state of stupor which is described as a catatonic state. Although the disease is described as functional, recent discoveries seem to suggest that there is some derangement of the blood chemistry. Treatment by insulin and the new tranquillising drugs has revolutionised the outlook in this admittedly serious disease. Indeed, some cases of psychosis are more easily treated than neurotic patients, since the former respond to physical methods, whereas the latter may require fairly prolonged psychotherapy (psychological treatment) and are less responsive to drugs.

In cases which do not respond to other methods, the brain operation known as *leucotomy* may be performed. Leucotomy is also performed to alleviate intractable pain, as in incurable cancer, but some of the ataraxic drugs (tranquillisers) are probably equally useful for this purpose. Leucotomy involves the severing of the connecting nerve fibres between certain areas of the brain, and the results are often favourable, but in fact the operation should be performed only in cases where the outlook is otherwise very poor; chronic severe neuroses, frequent attacks of manic depressive psychosis, severe chronic depression, and schizophrenia which has not responded to other forms of treatment. The operation reduces anxiety, fear, aggressiveness, and agitation, but may result in the less-desirable symptoms of apathy, impaired judgment, lack of self-control, and loss of initiative.

Schizophrenia developing in later life is likely to be less dramatic in origin, and the delusions tend to be more systematised—that is, they take a persistent form, which does not change from day to day. This type of the disease is known as *paraphrenia*. In those beyond middle age the rare but dangerous condition described as *paranoia* may develop in which there are no hallucinations and the only symptom is a completely systematised collection of persecutory delusions, which on recital may sound entirely convincing even to the ordinary doctor. Such people are dangerous precisely because they are so plausible, and they fill the ranks of the litigious, the troublemakers, and the political and religious eccentrics. One such patient known to the writer spent his life in a mental hospital from which he had parole, employing this to form a society propagating highly eccentric sexual and political beliefs. It says little for the intelligence of the general population that his meetings were invariably crowded out (although, of course, when one reads of the people who apparently believe that the various fictitious families on radio or television really exist, one need not be surprised at such examples of communal dottiness, even if one may despair of democracy).

Manic-depressive insanity is characterised by mood swings in which the emotions alternate between wild elation without obvious cause and equally causeless depression. However, the picture is not quite as simple as this; for phases of mania or excitement may occur without depression obviously following, or there may be a single attack of depression with no manic phases. The disease may be absolutely incapacitating, or there may be periods of relative normality; typically, then, manic-depressive insanity is a disease of alternating moods. The depression responds to electroconvulsive therapy or E.C.T., but mania is less responsive to treatment. However, it ordinarily remits of itself. Sometimes in middle age *involutional depression* occurs, and this in the vast majority of cases is cured by E.C.T. As in the case of schizophrenia drugs are increasingly used for depression.

Neurosis.

The main neuroses are anxiety neurosis, hysteria, and obsessional neurosis. *Anxiety neurosis* is an illness in which the main symptom (as the name implies) is anxiety. There is fear which rationally the patient knows to be groundless; there may be anxiety attacks, in which the heart pounds, the patient feels he is going mad, is unable to sleep, and worries "for no reason at all." In hysteria, anxiety is largely absent, but there may be apparently physical symptoms ranging from paralysis of the limbs to blindness, deafness, inability to write, and lapses of memory (the so-called hysterical fugues or loss of memory). Typical of *hysteria* is the fact that the patient is less worried by his symptoms than would be expected from their apparent seriousness; this is what the early psychiatrists described as "la belle indifférence." The reason for the indifference is simple—it is that the paralysed individual *wants* to be paralysed, the blind *want* to be blind, the deaf to be deaf (there are none so blind—or deaf—as those who don't want to see, or hear), and the person who doesn't want to write conveniently finds that he cannot.

Generally speaking, neurotic people are suffering from a failure to face up to reality. They are not physically ill and are largely the end result of a faulty upbringing. It is wrong to suppose that the only bad families are those in which the children are ill-treated; much the worst ones are those in which children are spoilt, the parents possessive, and the wrong kind of love is dispensed. Neuroses are the result of a conflict between primitive desires and what the individual has been brought up to believe he should be. For example, before an examination a student may develop a nervous breakdown because he fears failure when he has been brought up to expect success. The excuse, of course, is "overwork"—an entirely non-existent condition. With his breakdown he solves his problem, he avoids the fear of failing and preserves his self-respect: he has been ill. Similarly, the soldier with "shell shock" (another non-existent condition) has a conflict between his sense of duty and his fear of death, which again is solved by becoming ill. Or, to take a final example, a woman feels the duty to look after her ageing mother. But she also wants to get married. So she unconsciously develops a neurosis which says, in effect, "I should like to do my duty in looking after my mother, but unfortunately I am unable to." There is an unconscious rebellion on the part of the mind.

Neurosis, in effect, is not a disease—it is a self-inflicted injury, a form of maladaptation to life. The neurotic, no matter how much he suffers, does not want to get well; he has found some way of getting along, even if a foolish way, and he intends to keep it. Often his symptoms are the sort of excuse that say: "If only I wasn't ill what wouldn't I be able to do!" The neurotic is a person who is different and is afraid to be himself; his problem is a conflict between being "ordinary," "like other people," and being what he was supposed to be.

Obsessional Neurosis is a more severe type of neurotic illness; for although in anxiety neurosis we find such symptoms as phobias—irrational fears of open spaces, closed spaces, animals, and so on obsessional states are characterised by compulsive feelings that certain acts must be performed or certain thoughts thought. In a mild form we all have obsessions: we feel that we must walk on the spaces between paving-stones, that we must touch lamp-posts, and so on. But when this type of compulsion gets to the stage when we must go back several times to make sure the lights have been put out, when we feel the need to wash our hands every few minutes, become obsessed with numbers on cars or dates on coins, then it becomes a nuisance and requires treatment. The obsessional neurotic is' a person who feels that life must be controlled: he is "a creature who moves in predestinate grooves—he's not even a bus but a tram." His symptoms are an attempt to devise self-imposed rules which will control the unconscious desires of which he is so afraid.

Neurasthenia is an entirely imaginary condition allegedly due to exhaustion of the nervous system. Since no such condition exists, we need not bother with it. Neuroses cannot be treated by feeding the nerves (which are perfectly normal). They can be helped by such things as sedatives, but not cured. *Neurosis has nothing at all to do with disease of the physical nerves, so nerve tonics do not exist, and anyone who asserts that they do is a humbug.*

Psychopathic Personality is the term given to anyone who has different standards of behaviour from those generally accepted by society. Some of these unfortunates may be *inadequate*, that is to say, although perfectly intelligent, unable to earn their own living. Others are the *creative* people, who, as in the case of Van Gogh, did many eccentric things but also many productive things—Van Gogh was gifted, or cursed, with an intense sensitivity. Lastly, there are those who have what others regard as peculiar sexual habits. Of the first two classes nothing more need be said, and all that is necessary is to mention certain of the so-called sexual perversions. (When we say so-called the implication is not that none of these forms of behaviour is perverse but that some of them are carried out by otherwise quite ordinary people.) *Sadism* and *Masochism* refer to, in the first place, pleasure in inflicting pain and, in the second, to receiving pain. The pleasure is sexual, and it is incorrect to talk of cruelty in itself as sadism. Sadism is named after the Marquis de Sade, who suffered from this perversion, although he certainly did much less harm in his small way than numerous politicians or generals of our time, and masochism is named after the Austrian novelist Sacher-Masoch, who wrote books which, although unpleasant, were not notably more so than certain Sunday newspapers of today.

Masturbation is sexual self-stimulation. Needless to say, it produces no more *physical* harm than ordinary sexual intercourse—that is to say, none at all, although some people have the strange belief that every act of intercourse weakens the body and it has even been believed that each act shortens life by a specific length of time. This is rather illogical in view of the fact that most of the famous rakes have been noted for their longevity! Masturbation is almost universal in infancy, adolescence, or even in later life when other outlets are not available. It need only be a matter of concern: (*a*) when it is chosen in preference to normal sexual activity, or (*b*) when it is compulsive and excessive, since then it is a sign, not of sexual desire, but of severe underlying anxiety.

Homosexuality is, as presumably most people now know, an attraction between individuals of the same sex. Most people pass through a brief homosexual stage. Ordinarily this comes just before puberty when schoolgirls get "crushes" on older girls or teachers and schoolboys have similar feelings towards their heroes. The disposition, however, may be retained into adult life. Nowadays people take a much more tolerant view of homosexuality, accepting that what adults do (with consent) is their own business and that a male homosexual who seduces a boy under age should be treated in no way differently from the man who seduces an under-age girl. Male homosexual practices are no longer an offence if committed in private between consenting adults. Female homosexual practices have never been an offence.

All that remains to be said is that many of these conditions are treatable or, if not treatable so far as cure is concerned, they can at least be relieved. The world is full of people who are "different"; there are those who are different in the right way, who should take satisfaction from their achievements, and those who are different in the wrong way, who should seek expert advice. Since psychological treatment is time-consuming, it is not very easy to obtain it within the National Health Service, although group treatment has simplified the problem. However, any person with such difficulties would probably benefit from a discussion with his family doctor.

DISEASES OF THE SKIN.

The skin in the course of development before birth is particularly closely associated with the nervous system. It is therefore not surprising that so many skin diseases are influenced by emotional states. Other causes of skin disease are infections, glandular disorders, vitamin deficiencies, and the numerous conditions for which no cause has been discovered, but which presumably are due to metabolic disorders.

One of the commonest skin symptoms is *itching or pruritus*. It may accompany many different general diseases, for example diabetes and jaundice. It may also be troublesome during the menopause (the change of life in women), in old age, or in nervous conditions. Sedatives and sex hormones sometimes help the itching during the menopause, and there are ointments which may be useful.

Itching in the region of the anus and genital organs is relatively common. It may be caused by worms, by irritating vaginal discharge, or by sugar in the urine, as in diabetes. The alteration in the normal bacteria of the bowel which follows treatment with various antibiotics also often causes anal pruritus and soreness. In many cases however the itching has some psychological cause. In treatment it is important to avoid ointments and creams which contain a local anæsthetic, because these substances can cause severe allergic reactions if used for longer than a few days, and may thus make the condition much worse. Treatment with a local corticosteroid application is more effective and safer.

Parasites, such as the *scabies* mite or *lice* can cause severe and persistent itching. The scabies mite is very small, and since it burrows under the skin surface, is unlikely to be seen; it is the cause of itching most commonly between the fingers and on the front of the wrists. The itching is worst when the body becomes heated, as in bed. Treatment consists of painting the body from head to foot with benzyl benzoate application, followed the next day by a hot bath. Since scabies is contracted through close personal contact with an infested person it is often desirable for several or all members of a family to be treated at the same time, even though only one of them may be affected. Lice are specialists, one type of which affects the scalp, another the body, and a third the genital area. Head lice are destroyed by lethane, body lice by D.D.T (dicophane) powder, and genital (pubic) lice by shaving off hair and washing. Obviously, the clothes, especially in the case of body lice, should be disinfested, either by the use of D.D.T. or, if this is not available, by using a hot iron over the seams, which lice (for some inexplicable reason) seem to favour. Apart from the discomfort they cause, lice are dangerous as potential carriers of typhus fever.

Baldness, or Alopecia, is a very common condition, as is manifested by the extraordinary number of preparations advertised as curing it. When

many preparations are offered for the treatment of one condition it is a fair judgment to assume that none of them is likely to be effective. There are, in fact, two types of baldness; one, which is much the commoner, is hereditary, and cannot be influenced in the slightest by any treatment, the other, *alopecia areata*, is caused by nervous stress, and would recover in most cases by itself, whether one used a solution of soot and water or the most expensive "hair food." There is no such thing as a hair food, any more than there is such a thing as a nerve food, and although it is probable that hair hygiene may delay baldness, it certainly cannot prevent it. All hair tonics and "foods" are useless, and their uselessness is only equalled by their costliness. Those who have lost their hair and find it growing again after using some alleged tonic are people who have had *alopecia areata* and whose hair would have grown back anyhow. In women the hair often thins out soon after a pregnancy, but a few months later it usually returns to normal.

Seborrhœa is a condition in which there is over-activity of the sebaceous glands. The most usual form it takes is *dandruff*. However, it takes other forms, and those who have dandruff may also have rashes on the face, shoulders, and chest. In these areas there is a patchy, greasy, and often itchy, rash which does not clear up until the primary condition in the scalp is dealt with. The scalp should be washed with one of the modern sulphur-containing shampoos at least twice a week, and the affected parts on the face and chest can be dealt with by the use of a sulphur lotion (*not* on any account by greasy ointments). Seborrhœa is not in itself difficult to treat, but, since the condition depends on over-secretion of sebum, the skin lubricant, treatment may have to be persisted in during the years of early adulthood, when it is most active.

Erythema Intertrigo is, quite simply, the sort of irritation which occurs usually from excessive sweating under the armpits, between the legs, and under the breasts in women. All that need be done is to wash frequently and to dust the affected areas after washing with powder. This is the condition which, in the tropics, is known as "prickly heat" and elswhere as a "sweat rash." In some people *hyperidrosis* or *excessive sweating* is a problem, especially when the sweating is accompanied with body odour—the sort of thing that, according to the advertisements, "even your best friends won't tell you." There is little need for anyone in these days to suffer in this way: for the cosmetic firms have produced many highly efficient deodorants which not only control odour but also control the amount of sweating. Chlorophyll, which has been much advertised as removing odours, is effective when applied directly to surfaces which give off an unpleasant smell. It is however ineffective when taken by mouth, and does not prevent body odours. Stale sweat smells bad because it is decomposed by bacteria, and this type of body odour can be largely prevented by preparations containing a harmless antiseptic such as hexachlorophane and an anti-perspirant such as aluminium chloride (see *Which*, February 1960).

Erysipelas is an infection of the skin caused by the hæmolytic streptococcus. It begins as a red, raised area anywhere on the body where the germs have been able to enter through a small crack or cut in the skin. The red area advances and spreads over the body until the disease is got under control. Erysipelas is very infectious, and those who look after the patient should wash their hands throughly after contact. At one time the disease used to spread as an epidemic throughout the hospital wards, but this is very rare nowadays. Treatment is, of course, a matter for the doctor.

Chilblains are common in cold weather, especially in those with poor circulation. Ordinarily they occur in the toes and fingers, but may appear on the nose and ears. The part affected becomes swollen, dusky, and there is pain and itching, sometimes leading to ulceration. Protection of the body, especially the hands and feet, from cold is the best and the only really effective way of preventing chilblains. Warm lined gloves and footware, and warm stockings or trousers should be worn outdoors. Adequate heating of rooms is essential: a temperature between 18° and 21°C is recommended (65°–78°F). Most tablets, medicines, ointments, or creams for chilblains are useless. A skin affection caused by heat is rather grandiosely described as *erythema ab igne*, and is frequently seen on the legs of ladies addicted to roasting their legs before the fire. It takes the form of red patches on the front of the legs and can be removed only by avoiding the cause.

Dermatitis means "inflammation of the skin," and therefore the word could be, strictly speaking, applied to any skin disease. In fact the term is used almost interchangeably with the term *eczema*. There are three main types of dermatitis or eczema. The first, *primary irritant dermatitis* results from injury of the skin by some powerful chemical, such as strong alkali or turpentine. The second, *contact dermatitis* is due to sensitisation of the skin to some substance which is normally liable to cause this type of allergic sensitivity; examples are nickel (in jewellery and suspender buckles), epoxy resins, rubber additives, primulas and chrysanthemums, and even ingredients of cosmetics. Contact dermatitis may continue for a long time, even after the patient is no longer in contact with the offending material. The third type is often called *constitutional eczema*. Although the skin is apt to react adversely to various irritants and sensitisers the major part is played by the personality, and there is often a history of eczema, hay fever or asthma in the family. Treatment is more difficult, but local corticosteroids and tar, sedatives and psychological treatment can be of great help. Infantile eczema also belongs in this category, but in most patients it disappears as the child grows up.

Impetigo is an infectious skin disease caused primarily by the streptococcus, but later often infected with staphylococci. It usually occurs on the face, and takes the form of blisters filled with pus on a red base; when the blisters burst their place is taken by yellow crusts. Impetigo is very infectious and easily spread by the fingers, dirty towels, or cloths; therefore, one of the first necessities is to prevent infection of others or reinfection of oneself by avoiding scratching and using a different towel each day, which must on no account be used by anyone else. Treatment is simple with an antibacterial ointment, so the main issue is prevention of contamination.

Sycosis or "Barber's Rash" occurs in men, and is similarly treated.

Urticaria or *Nettlerash* is a familiar skin disease in which itching weals appear on the skin, usually for no obvious reason. It is not infectious, and can be caused by nervous stress, certain drugs, allergy to some foods, or even exposure of the skin to cold. In some people it is possible to write on the skin with a fingernail: the "writing" appears in the form of weals. This is known as *dermographism*; it occurs in many normal persons as well as in many patients with urticaria. The antihistamine drugs are the most useful in the treatment of urticaria. Urticarial swelling of the tongue or throat must however be relieved at once and is treated by an injection of adrenaline.

Acne, or "*Blackheads*," is a condition found on the face and shoulders; its appearance is so familiar that no description is necessary. Acne is one of those conditions which is the end result of many factors. There is, first, a greasy skin, the result of glandular upset (which is why the disease usually occurs in adolescence); secondly, there is infection of the skin; and thirdly, there is blockage of the sebaceous ducts, which ordinarily allow the grease from the skin to pass out on to the surface. Since the condition starts with excess secretion of grease, ointments should never be used, and probably the best applications are drying lotions containing some sulphur preparation which inhibits secretion of grease. The face should be frequently washed, and it is possible now to obtain detergent solutions which are both antiseptic and prevent grease formation. In severe cases ultraviolet ray treatment may be necessary.

Rosacea. As has already been implied elsewhere, although the wages of sin may be extremely unpleasant, the wages of extreme virtue may be no less troublesome. Thus *rosacea*, in which the nose and cheeks become red and greasy and the skin coarsened, occurs alike in chronic alcoholics and elderly ladies with no vices other than a preference for strong tea. Both cases are associated with indigestion, since, regrettable as it may seem, strong tea and alcohol are about equally liable to cause the gastritis which may be at the root of this complaint. However, in many patients the chronic flushing is caused in other ways and psychological factors are important.

Lichen Planus is one of the numerous skin diseases which seem to be due to nervous states of tension. It may occur on any part of the body, but is most common on the front of the forearms and legs. The rash takes the form of nodules which are lilac in colour and have a dent on the top; when these disappear a stain is left behind. There is severe itching. Treatment is a matter for a doctor, as it also is in the case of *psoriasis*, a very common disease of largely unknown origin, which is extremely resistant to treatment. It tends to run in families. It takes the form of slightly raised papules, usually on the elbows and knees; typically the papules are covered with dry, silvery-looking scales. Apart from the rash, the patient is usually in perfectly good health and there is no itching. Many drugs have been used in psoriasis, notably chrysarobin, and while it is not difficult to cause the rash (which may occur anywhere on the body) to disappear in one area or even in all areas for a time it has a strong tendency to return.

Warts, or *Verrucae* are familiar enough. They are caused by a virus, and are, theoretically at least, contagious (although having removed many warts, the writer has never found them contagious). Most frequently they are found on the hands, but may occur elsewhere. Treatment is best carried out by a doctor, who will use a cautery, a caustic carbon dioxide frozen into "snow." A curious feature of the common wart is that it can sometimes be caused to disappear by suggestion, which is presumably why so many old wives charms are not necessarily without effect. Different altogether from the common wart is the *plantar wart*, which occurs on the soles of the feet and often causes a good deal of discomfort. It is best dealt with by a chiropodist or in bad cases by a skin specialist since it is highly infectious.

Ichthyosis is a disorder of horn formation with which some unfortunate people are born. The oil and sweat-producing glands do not function well and the skin is dry and scaly like the skin of a fish. It is, however, possible to help the condition, which does not affect the general health, by frequent alkaline baths to wash off the scales, and the subsequent use of lanolin to replace the lacking oil. Large doses of vitamin A seem to help in some cases, and there have been reports in the medical Press of cases being helped by hypnosis; this, however, is very much a matter for speculation.

Cancer, Rodent Ulcer, and Cysts. Cancer of the skin occurs mostly in old people, and takes the form of what is described as an *epithelioma*. It is most common on the face or hands, and usually appears as a nodule which breaks down and produces an ulcer. The glands may later be affected, but such cancers can almost invariably be cured unless a considerable time has elapsed during which they have been neglected. *Rodent ulcer* is a form of ulcer which appears on the inner corner of the eye or the side of the nose in old people. It does not spread over the body, but acts by eating into the tissues in the area where it has started. X-ray or operation is necessary, but the outlook is good. *Cysts* on the skin are due to blockage of the sebaceous glands. They may become very large, and are best removed, as they may become infected. They do not turn into cancer, and there is no such thing as "male" and "female" cysts. It does sometimes happen that *moles*, especially of the bluish-black type, may become malignant, so it is perhaps best to have them removed surgically when they exist. *All moles which change in appearance or size should be at once referred to a doctor.*

Skin Grafts.

These are a very complex subject which can be only briefly discussed here. They are used basically for a number of conditions in which large areas of skin have been removed from the body, as in burns or serious accidents. In other cases, as in plastic surgery, grafts may be used to make a new nose, eyelids, and so on. The following are the main types:

Pinch Grafts are small, circular pieces of skin cut from some other part of the body. (The former method of using grafts from another person has been given up almost completely, since such grafts—except in the case of identical twins—never "take.") The small pieces are laid on the area without skin and gradually grow together. *Split-thickness grafts* are grafts removed from another part of the body by an instrument known as a dermatome, which cuts sections about 4 in. by 8 in. containing part of the deep layers of the skin.

In *Full-thickness Grafts*, on the other hand, the whole thickness of the skin is removed from elsewhere and applied to an area which has to bear friction or heavy weights, such as the hand or the foot. Lastly, and this is largely used in plastic surgery, there is the *Pedicle graft*, which, unfortunately, although it is certainly the most exciting type, is rather difficult to describe. Briefly, if one, for example, wants to make a new nose, one cuts an area of skin and underlying fat about 2 in. wide and 5 or 6 in. long in the abdomen. One end, however, remains attached so that it gets adequate blood-supply. The problem is how to get this tissue to the nose, and this is done by a complicated process of leap-frog. First, the free end of the graft is attached to the forearm, whilst its "root" remains in the original site, and when it begins to grow and get its blood-supply from the arm, the original "root" is cut. So we now have a "sausage" of tissue attached to the arm. The arm is then lifted to the face and kept firmly in position there until the new free part becomes attached. It is then detached from the arm, modelled to the correct shape, and grows where the nose used to be!

DISEASES OF THE JOINTS.

Rheumatism is a word most doctors wish did not exist. This is partly because they do not understand it, but mainly because it is a condition which strictly does not exist: which is small comfort to the many millions of people who are more or less totally incapacitated by it. The truth is it is used for a hotch-potch of very real diseases, in all of which there is pain and stiffness of what is called the musculo-skeletal system, *i.e.*, the muscles and the joints. It may mainly involve the joints, in which case it should have been called arthritis; or it may involve other structures near the joints like tendons, muscles and fibrous tissue. Joints may either suffer from inflammation or degeneration or both, and the trouble may be acute or chronic or both; so it is easy to see what a mix-up the subject becomes, especially when we must include the joints of the spine as well as the limbs, feet and hands.

A good deal of arthritis used to be due to various germs, but these types are much less common now that the infections causing them have become rarer or better treated. They used to include gonorrhoea, tuberculosis, septic joints, syphilis, brucellosis, typhoid fever, dysentery and so on. The importance of *Rheumatic fever*, which is a reaction to an infection (streptococcal sore throat) rather than being actually caused by the streptococcus, is not because it involves the joints. This arthritis quickly clears up, but there may also be disease of the heart which may be serious and has been described on P28.

Rheumatoid arthritis is a completely different condition in which there is non-infective inflamma-

tion of connective tissues throughout the body. In the joints, the normally smooth, lubricated synovial membrane lining the joint cavity becomes scarred, leading to distortion, especially of smaller joints like those of the hand. Another characteristic feature is its capacity to vary in severity from time to time, with a strong tendency to unexplainable periods when it gets better or worse. This makes it extremely difficult to know whether any form of treatment is being useful, since any response may have occurred in any case. As in all diseases which behave like this, especially those in which medical men are also baffled, there are almost as many theories and treatments as there are doctors. It has never been satisfactorily shown to be caused by infection, faulty nutrition, "glands," emotions, personality disturbance, nor is it convincingly inherited. The best current theory links it with an increased sensitivity reaction, perhaps to the body's own tissues, known as "autoimmunity." From the patient's point of view there is swelling and deformity of the joints with tenderness on pressure and pain on movement. Treatment involves a lengthy and complicated regime of rest, relief of pain with aspirin, exercises and the application of heat, with attention to general physical and mental health. At some stage adrenal corticosteroids (cortisone and its derivatives) are often tried, but although these can give great relief they have to be very carefully used to avoid very unpleasant side-effects.

Osteoarthritis is another completely different condition closely related to the normal processes of aging. Therefore it occurs in older people than those with rheumatoid arthritis, and tends to be in larger, weight-bearing joints of the spine, hips and knees rather than in the hand; although the end joint of the fingers is commonly affected. Hard wear and tear, especially that caused by overweight, or injury may be the beginning of it. It is *not* due to diet, and dieting has no part in treatment except in those who need to slim. Physiotherapy, including heat, is helpful. It is not such a relentless condition as rheumatoid arthritis and patients should be reassured about this.

Fibrositis and other vague forms of "rheumatism" are very often manifestations of psychological problems. This does not make them any less real, but it directs treatment towards the mental state rather than to the joints and muscles.

EYES, EARS, NOSE AND THROAT.

Diseases of the *eyes* are very specialised and only very general information can be given here. The most common is inflammation of the conjunctiva causing redness and usually due to infection or some irritant substance or dust. If it persists and leads to hard crusts of yellow pus on waking in the morning, get it seen by a doctor for treatment probably with antibiotics. First-aiders are usually instructed how to remove small particles of grit from under the lids. It is important that these should not scratch the front of the eye—your window on the world—as this may lead to scarring and poor vision. So, above all, do not rub them in. Also, if you are fishing one out of someone else's eye, see it before removing it. Do not have a general sweep round in vague hopes of finding it. If in any doubts, obtain skilled help. Remember the eyes are part of the brain: the only visible part. Perhaps this is why people's eyes are so revealing.

Conditions such as glaucoma, cataract and disorders of vision are beyond the scope of this section.

Foreign bodies in the ears and nose are a constant minor problem with children. In these cases, whether they be peas, beads or peanuts, do *not* attempt to fish them out. They are doing no harm where they are, provided the child can be prevented from fiddling with them. Get him to a doctor who knows far better than you do about the delicate structures of the ear drum or the internal nose just behind the object, and has the proper gadget to get it out.

Sore throats are a nuisance we all have to put up with from time to time. If they last more than a few days they should be treated professionally. Persistent or recurrent sore throats are often due to over-eager treatment with antibiotics not allowing the body to learn how to fight the germs itself. Never prescribe antibiotics for yourself, especially in lozenge form, and only expect your doctor to give them when other measures have failed.

Tonsils and their inflammation are a problem, as well as a source of easy money for the privately operating throat surgeon. It is comparatively rarely that they should be removed, yet every year hundreds of thousands of innocent children are subjected tho this ritual cruelty to satisfy the misconceptions of their parents and the greed (or ignorance) of some surgeons. Of course there are many children who benefit so much from having tonsils out that the operation (which has real dangers) is worth doing. But please allow your doctor to decide if it is necessary, and do not pressurise him into recommending it. (The same is true of *circumcision*, for which there are no hygenic, and practically no medical indications. If your reasons for inflicting this cruel assault on your little boy are religious or emotional, then please admit it: but do not pretend it is "necessary" or even medically helpful.)

DISEASES OF WOMEN.

The *internal sexual organs* of a woman, like the urinary system, can best be described as shaped like a capital Y. At the tips of the arms of the Y are the female sex glands, the ovaries: the two arms running downwards are the Fallopian tubes: the point where the arms meet is the womb or uterus: the single leg of the Y is the vagina. These are the *primary sexual organs* of a woman and they undergo regular cyclical changes in response to the control exercised over them by the pituitary gland, situated in the base of the skull. This control is mediated by chemical messengers (hormones) secreted into the circulation. The ovaries also secrete hormones, œstrogen, and progesterone, and a delicate hormonal balance is maintained between the pituitary gland and the ovaries. Each month an egg cell (ovum) matures and is released from the ovary, usually midway between two menstrual periods: the ovum is wafted along the Fallopian tubes by waves of contraction and if fertilised embeds in the lining of the uterus which has been conditioned to nourish it by the ovarian hormones. If it is not fertilised the ovum escapes from the uterus, altered hormone levels then cause the lining of the uterus to be shed (this is menstruation), usually about 14 days after ovulation. After menstruation a new cycle begins; another ovum matures and a fresh lining grows in the uterus. These cyclical changes recur from puberty to the menopause. Menstruation does not occur during pregnancy, of which a missed period is often the first sign. However, women do miss periods even though they are not pregnant, and this usually means that some minor and temporary change has occurred in the hormone balance. If three consecutive periods are missed it is wise to consult a doctor.

The *breasts* are called *secondary sexual organs* and are also under the influence of the ovarian hormones. Two conditions which need treatment are *mastitis* and *cancer of the breast*, both of which are characterised by lumps within the breast tissue. Mastitis may be uncomfortable but is not dangerous and can be treated medically, whereas cancer is more serious. The distinction between mastitis and cancer can only be made by a doctor and any woman who discovers a lump in her breast must seek medical aid *at once*.

Abscesses also occur in the breast, nearly always when the mother is feeding her child. Here again, a lump appears, the breast becomes red and very tender, and the woman may be feverish. Treatment with antibiotics is sometimes successful, especially if the mother consults her doctor quickly, otherwise treatment is by a small operation.

The Ovaries. The two commonest diseases of the ovaries are cysts and disorders arising from

hormonal imbalance. The symptoms of ovarian disease are usually abdominal or low back pains, and heavy and painful loss during the periods, which may become irregular. These signs should be taken as a warning to consult a doctor.

The Fallopian Tubes. Infection of the Fallopian tubes is called salpingitis. The membrane lining the tubes is continuous with the lining of the uterus, hence an infection is rarely confined to a circumscribed area in either the tubes or the uterus, and pelvic inflammatory disease is a better name for this condition. Pelvic inflammatory disease often follows an abortion, or childbirth where part of the afterbirth (placenta) has been retained, or can spread from an infection in a nearby organ, for example the appendix. Infection is sometimes conveyed by the blood from another septic source in the body. The gonococcus is another cause of infection. The disease is characterised by pain and tenderness in the lower part of the abdomen, accompanied by fever, general malaise and frequently (but not invariably) a vaginal discharge. The treatment of pelvic inflammatory disease is usually medical and is the same irrespective of the primary site of infection. Before the introduction of antibiotics the disease often became chronic and the Fallopian tubes were frequently blocked by a cicatrising scar, a cause of subsequent sterility.

The Uterus. This is a hollow muscular organ and both its musculature and its lining membrane can be the site of disease. *Fibroids* are non-malignant muscular tumours which develop in many women. The main symptom is a heavy menstrual loss and surgical removal of the uterus (hysterectomy) is often necessary. This is a major operation, but modern anæsthesia and operative techniques minimise the discomfort. Hysterectomy does not impair sexual pleasure, but no more babies can be conceived. Infection of the lining of the uterus is usually part of a generalised pelvic inflammatory disease (*see* Fallopian tubes).

Cancer of the Uterus and Cervical Smears. The uterus is pear-shaped and consists of a body and neck. The wide end is uppermost (the body) and the narrow neck (cervix) projects into the top of the vagina. Cancer of the cervix is commonest in middle-aged women who have married young and have had a large family; cancer of the body of the uterus usually occurs after the menopause and is most common in childless women. The symptoms are variable and it is sufficient to emphasise that any woman who has unexpected bleeding, especially after intercourse, whether her periods have stopped or not, *must* see her doctor at once. The treatment depends on individual circumstances, but is usually by operation. It is now possible to detect cancer of the cervix long before symptoms develop and at a stage when the disease can be eradicated by a relatively small operation. This early detection has been made possible by the development of exfoliative cytology. Cells taken from the cervix (without discomfort to the woman) are examined under a microscope. This test is popularly known as the "cancer test" or "cervical smear." A cervical smear is often taken as part of the routine gynæcological examination by consultants, general practitioners, and family planning doctors, and is also being included in some population screening programmes. It is a big step forward in preventive medicine and may ultimately solve the problem of cancer of the cervix. Every woman between the ages of 25 and 60 should seize any chance to have this test done.

Prolapse means a sagging down of the uterus into the vagina and the cervix may even appear at the outside. It is a result of frequent childbirth and laxness of the ligaments which support the uterus: weakness of the vaginal walls often occurs at the same time. The symptoms of uterine prolapse are low back pain and a heavy dragging feeling in the lower abdomen: these are often overshadowed by the distressingly embarrassing incontinence which results from lax vaginal walls. The stress of only a sneeze, a cough, or a giggle often causes the involuntary escape of urine. The cure is operative and very rewarding.

Dysmenorrhœa or pain with the periods, is very common and most women experience this symptom at some time or another. Very often a girl's first periods are troublefree, but dysmenorrhœa develops after a year or two: this suggests that a psychological element is involved. Dysmenorrhœa is a symptom which has many varying causes, and the sensible thing to do, if pain is troublesome, is to see a doctor.

Amenorrhœa means stopping of the periods in a young woman. It may signify pregnancy or glandular disease or it can be purely psychological.

Abortion, or its more acceptable name, miscarriage, describes the spontaneous or induced termination of a pregnancy before the fœtus (baby) is able to survive. A baby cannot live unless it is born after the twenty-eighth week of pregnancy, though many infants born at this time die. The two main symptoms of abortion are bleeding and abdominal pain. Any bleeding occurring during pregnancy ought to be reported at once. Pain starts in the back and lower abdomen and is usually spasmodic in character, and like colic it works up to a peak and then temporarily passes off. Any pregnant woman with pain and bleeding should go to bed at once and send for her doctor. When doctors are convinced that a pregnancy should be terminated then an abortion by safe surgical means may be performed in hospital.

CONTRACEPTION.

If a couple intends to practise birth control expert advice should be obtained from their family doctor or family planning clinic. The matter of whether or not a baby is born is too important to leave to chance. The method chosen must be effective as well as acceptable to the couple concerned, and the extent of the choice only emphasises the fact that the ideal contraceptive which is best for every couple at all times has yet to be discovered. The only method which is 100 per cent. reliable is abstinence. If the male seed (sperm) fertilises the female seed (ovum) then pregnancy results. Contraception is only effective if this union is prevented. A couple can achieve a measure of contraception without the help of pills or appliances if the husband practises *coitus interruptus* or they rely on the wife's "safe period." *Coitus interruptus* (when the man withdraws before emission occurs) is a thoroughly unreliable method which often leads to psychological difficulties in both partners. The "rhythm" or "safe period" method relies on estimating the time of ovulation and abstaining from intercourse during this time. This is at best unreliable, though its effectiveness can be improved by keeping careful records of the body temperature on waking each morning as the temperature rises once ovulation has occurred. The interpretation of these temperature records needs care and couples who must rely on this method can obtain expert advice from, for example, The Catholic Marriage Advisory Council, or a family planning clinic. *Barrier methods* prevent the sperms from reaching the ovum and can be used by the man (sheath or condom) or woman (cap or diaphragm): the reliability of the barrier is greatly increased if it is used in conjunction with a spermicidal cream, jelly, or pessary. A great many women have found that the *oral contraceptive pill* is ideal for their needs: it is the most æsthetic means of contraception and offers the most complete protection against pregnancy. Oral contraceptive pills contain chemical substances (œstrogen and progestagen) which replace the hormones normally released from the ovary while an ovum is developing. Ovulation does not occur, and without an ovum there can be no pregnancy. Pills must be taken strictly as directed as the dose is the lowest that will provide effective contraception and missing a tablet may result in pregnancy. Side effects sometimes occur (for example, nausea, breast discomfort, headaches,) but usually decrease after a few cycles of medication. Newspaper reports

of the deaths of young women taking the pill have caused widespread concern. These tragedies have followed blockage of a blood vessel (by thrombosis or embolism) and have been carefully investigated, and the conclusions are that the number of such deaths is small and does not differ from the number which would probably have occurred in any case. No satisfactory pill for a man has yet been developed. In the newest method of contraception a small plastic *intra-uterine device* (loop, bow, or coil) is inserted into the womb. Once inserted it can be forgotten: a tremendous advantage to many different peoples and societies. It is not as effective as the pill but is more satisfactory than barrier methods. This intra-uterine device is not suitable for all women and is usually not recommended to women who have borne no children or who have very heavy periods. However, careful selection of suitable women has resulted in a high proportion of satisfied users. The search for the ideal contraceptive continues.

Vasectomy (a form of sterilisation) may now be performed under the health service on a husband in the interests of the health of either husband or wife.

PART III. SPECIAL TOPICS.

INFANTILE UNDERNUTRITION AND THE BRAIN.

A good deal of research is currently being devoted to the question whether early malnutrition can play any part in reducing an individual's ultimate human achievement. In this context "achievement" means higher mental function, and "reducing" implies an attainment lower than was his original genetic potential.

The position to date is that there seems little doubt that it can, if the malnutrition is severe and of sufficient duration; and if it occurs at a certain period of brain growth. The outstanding unanswered questions are therefore (*a*) whether undernutrition plays a *significant* rôle in this respect especially in our more developed countries, (*b*) what is the period of human growth and development during which nutrition is particularly important for brain growth? and (*c*) is the lack of any specific nutriment (*e.g.*, protein) an important feature?

We shall first discuss the evidence that there is an effect and then consider the answers to (or rather the informed speculations about) these last three questions.

Early Malnutrition Permanently Reduces Mental Potential.

There has probably always been a feeling among those working in underprivileged communities that impoverished children grow into less well endowed adults, and this was probably as much so in North West England during the 19th cent. as in the more underprivileged parts of the world today. Indeed the chances are that the matter is comparatively or totally unrelated to ethnic group, nationality, or geographical region and overwhelmingly related to environmental (including nutritional) underprivilege. This is why the expression "underprivileged community" is to be preferred to "underdeveloped country", since it opens our minds to the present-day existence of pockets of underprivilege, and hence similar effects on children in such communities within even the richest country in the world.

These appearances of apparent dullness and their possible causes and associations are, however, difficult to attribute to nutritional causes and, until recently, have really not begun to be adequately observed. Apart from the difficulties of measuring human achievement, the main problem is that such communities are always underprivileged in many more ways than nutritionally; and so many of these ways are also known to stunt the growth of the intellect.

A moment's reflection will serve to make one realise that a malnourished child will usually (though not invariably) be living in a family which is desperately short of food for the mind as well as for the body. The drabness of the slum home whether in the industrial town or in the Asian village can provide a poor level of stimulus to the developing mind. Parents who are themselves uneducated, and living at or below subsistence level, are unlikely to provide sufficient non-nutritional input, let alone sufficient food. Where this also results in a chronic shortage of tender, loving care (T.L.C.) this will surely clobber the intellectual development of a child even more effectively than lack of schooling. How, then, to show a separate rôle for malnutrition when lack of food may be only one-twentieth part of the total social and emotional and medical impoverishment?

There are other technical problems for the research. How are we to measure human achievement? Is I.Q. in any of its sophisticated variants a sufficiently meaningful index? Certainly not, most would say, but it is probably all we have; and even then we still have to overcome the problem that we cannot sensibly compare the same tests of "intelligence" on children in an underprivileged culture with those in our own. The whole problem of cross-cultural applicability of psychometric tests has to be solved—or better still avoided by carefully choosing our comparison groups from the same culture. *See also* Q28.

Various designs of investigation have been used by the many teams of researchers in different parts of the world to overcome these and other problems. All have been in some measure defeated by the problem. The most successful is probably one which has only just begun to be published. This new research has been led by Herbert Birch and his wife and colleagues in New York and Jack Tizard of the Institute of Education in London. Some of their findings will now be outlined.

The Jamaica Study.[1]

The British Medical Research Council has had a very distinguished Unit investigating infant malnutrition in Jamaica for many years. Here they have treated many severely malnourished babies and children in hospital, and Jamaica is therefore one of the few places in the world where individuals can be found in later childhood whose early malnutrition as babies has been adequately described and documented to the high standards needed for research, whose treatment was the best available, and who can be subsequently traced. In most underprivileged communities these essential criteria cannot be met, for obvious reasons. Birch and his colleagues were able to find 80 such children years after they were successfully treated for their nutritional disease. They were chosen for reasons which will emerge for having been severely malnourished before the age of 2.

To overcome some of the difficulties of comparison mentioned above, they chose two comparison groups of similar age and sex in which the children had not suffered such severe malnutrition. One consisted of brothers and sisters of the previously malnourished children: the other of their unrelated schoolmates in the same classes at school. In this way they have probably come the closest yet to "controlling out" the variables of culture and heredity. Various sophisticated observations were made on their I.Q. performance and on their family and social circumstances.

The stark fact from their first published paper is that the previously malnourished children have grown up with an apparently permanent very substantial I.Q. deficit when compared both with their siblings and with their schoolmates. It is interesting that the siblings did virtually as well as the unrelated schoolmates; and the simplest conclusion is that the diminished achievement of the previously malnourished children was due primarily to malnutrition before the age of 2.

Some scientists will continue to object that this does not constitute absolute proof, and of course it does not. Neither would Birch claim that it did.

But taking into account all the difficulties, it is probably as near to direct proof in a human community as we shall ever get and is probably a much more satisfactory demonstration than any other to date.

Many more important data were collected in this study which still await formal publication.[2] For example, some attempt was made to measure the non-nutritional quality of the homes, which were then roughly divided into "good" and "poor" from the point of view of whether any notice was taken of the children. Did they have toys? Were they taken out on trips and shown things? Was there radio in the house? Did they live in isolated unstimulating country or in the bustling town etc. In this way four groups of children were identified: (*a*) good stimulus, good nutrition; (*b*) good stimulus, poor nutrition; (*c*) poor stimulus, good nutrition, and (*d*) poor stimulus, poor nutrition. The fascinating, if expected result shown by the average I.Q.s in these groups is that (*a*) scored most, (*d*) scored least, and (*b*) and (*c*) scored *about equally* and somewhere mid-way between (*a*) and (*d*). In other words both the low quality of the non-nutritional stimulus as well as the poor nutrition contributed to the low performance in group (*d*): each played its part; and each could partially compensate for deficits in the other: *but not completely.*

However one of the most telling observations was that when the school children were asked to write down the names of the three children in their class they most liked to play with, the previously malnourished children never appeared in any child's list. And this may be an index of the most dreadful consequence of all.

Are These Findings Significant for the Richer Countries?

Leaving aside the grossly impoverished communities still languishing even in some of the richest countries, what about the ordinary children of Manchester, London, Leeds and Sheffield? And here we have to resort to pure guesswork. The degree of nutritional growth retardation in such cities (leaving aside the complicating issue of obesity-malnutrition in babies) is plainly less than in much of the Third World. Nevertheless it exists, and to know whether it plays any real part in determining our ultimate achievement, we must probably have recourse to the unsatisfactory "linear" hypothesis. It is rather like estimating the hazards of nuclear fall-out or X-irradiation or of some kinds of drug toxicity which are impossible to determine directly. We know that a large exposure will kill, a somewhat smaller one will maim, less still will affect some people, and from this decreasing, linear dose–response curve we are left wondering whether the even smaller "doses" most of us are exposed to do harm? The scientific comment is that questions about the lower end of the curve are almost philosophical, so difficult are the effects to measure.

The same is probably true of early malnutrition and the brain. The most severely malnourished babies in the world may occasionally be found in the urban poverty of Central and South America. These babies weigh little more than their birth weight at one year of age. Most of them do not survive that long, but increasing numbers now do, and they are frankly mentally retarded when they grow up. The lesser, but still severe malnutrition of the Jamaican children mentioned above still leaves serious I.Q. deficits, but these usually fall short of frank retardation. Can we extrapolate the line downwards linearly, or does it level out? The answer is probably not ascertainable by known research techniques, but if any individual mother wishes to do the best for her individual baby, a wise guess is probably that the relationship does continue to hold good at the lower levels.

At What Age is Brain Growth Most Vulnerable to Nutritional Growth Restriction?

Here the answer is easier, though still not as clear as we would like it. It is easier because in this respect our human brain growth remarkably resembles that in other animals: and for them we know some of the answers. The most vulnerable period in this sense is one known as the brain "growth-spurt": a time beginning when the brain quite suddenly begins to grow very fast and ending when its growth levels off towards adult values. Recent research has identified this period in humans as beginning about the middle of fetal life and not ending until about the second postnatal year.[3] It has further been shown,[4] this time in animals, that the growth processes comprising the brain growth spurt have only this one opportunity to develop properly. If conditions are not good for these events to occur at the correct age, there is no catching up later even if good conditions return. Specifically, if poor nutrition retards bodily growth at the time when the brain is going through its growth spurt, the brain will grow less well in many important particulars with distortions and deficits which are not completely recoverable.

The guess we must therefore make, in the light of all the evidence, is that the vulnerable period for the human brain, from mid-pregnancy until about the age of two, is an age when we have an opportunity to ensure proper growth of the brain by promoting proper bodily growth; and that it is important to avoid growth retardation over a substantial proportion of that time.

How to Ensure Nutrional Protection for the Developing Brain.

This of course is the question of greatest interest to nutritionists, and the specific answer is hopelessly elusive. In general the answer is that the diet should probably be such as to ensure good, fast but non-obese growth throughout this period and to be guided by the baby's growth performance rather than by our very elementary theoretical knowledge of his dietetics. A good deal of direct research into baby growth and its outcome remains to be done. It is likely that some of us have been concentrating too much on laboratory theories about supposed nutritional requirements and not enough on the proof of the pudding—the proper growth of the babe!

At least from the point of view of brain growth there is no evidence whatever that fish, glycerophosphates, essential fatty acids, or any other dietary constituent is specifically good. The brain synthesises most of its own components within itself from quite elementary precursor substances abstracted from the circulating blood. Provided these are available and the general growth trajectory is good (which amounts to the same thing) we can safely forget about the details of the dietary constituent. The brain is not separate from the general plan of bodily growth. It is part of it; but it is probably the most important part in the last third of pregnancy and the first two years or so of life.

The things which enable normal people to realise their full genetic potential as human beings are almost exclusively environmental. The range of variation in achievement produced by variation of environmental conditions is probably enormously greater and more important than the range attributable to our genes. One of these environmental variants (perhaps even only a small one) is developmental nutrition: and it must even be conceded that a nutritional deficit, especially in privileged communities, can probably be largely compensated for by enough good quality stimulus in the non-nutritional environment. Nevertheless, if our ultimate achievement is eventually made up of a large number of environmental plusses and minuses it will clearly be wise for any mother to make as many of them plusses as possible. In this sense proper baby nutrition must be important to the developing brain, and she will be doing her best for her child's brain if she arranges for him to grow well both before he is born and in his first years. None of this may be as important as T.L.C. It is simply a matter of covering all the options and having as many "plusses" as possible.

SLEEPING AND DREAMING.

An alien from some distant planet where biological life had never appeared might be surprised at the strange goings-on he found on earth. He would see creatures of a great variety of shapes and sizes, some cumbersome and armoured, some light and streamlined, others equipped with weapons for biting and tearing, all chasing around trying to eat each other. He would conclude that life on earth was very dangerous, but before going home he might notice a characteristic habit of these creatures seemingly at odds with the relentless duel they appeared to be engaged in. Quite frequently they would drop their neurotic alertness and, almost incredibly, lapse into a period of quiet with sense organs damped down, muscles inactive, and worst of all, their control centres seemingly switched off.

At this point the alien might decide that beings on such a planet which so carelessly let their essential defences drop didn't deserve to survive long, and assume that this dangerous "switch-off" probably signalled the onset of some internal process, not obvious to the outside observer, which must be of tremendous importance to the creature's well-being. His final surprise might come when he tried to ask the most intelligent of the animals what it was that was so important, and found that they simply didn't know.

And this happens to be the truth, for Man has made amazingly little headway into understanding sleep (which is, of course, the switch-off an alien would have observed), although taken on average he devotes one-third of his life to it. No doubt this is because sleep, by virtue of its own special properties, resists introspection—we cannot study it in ourselves without disturbing it. Furthermore it is a period when *nothing* seems to be happening, barren of thought and memory and yet inherently strange and enveloped in mysteries to which Man has frequently tried to provide answers. In this article we will look at some of these answers, note their general inadequacy, and consider some new facts and a fresh approach, which suggests that one of the main mysteries may be in the process of being unravelled.

Broadly speaking, the various approaches attempting to explain sleep (and, of course, the dream) fall into three main groups that the writer has called: (1) The Commonsense; (2) The Fantastic; and (3) The Psychoanalytic.

The Commonsense.

This theory states that the sole or principal reason for sleeping is to allow us to rest, and, alas for simplicity's sake, it just doesn't happen to be correct. True, there's something very tempting in the idea—after all we do switch into sleep after a period of "feeling tired," and wake in the morning with this feeling altered. What more reasonable than to assume that the point of sleep was to rest the body after the doings of the day? The trouble is that from a physiological point of view sleep is *not* necessary to rest tired muscles and aching bones—a period of relaxation in an armchair or stretched out on a bed *without* unconsciousness intervening is quite sufficient to allow the body's physical functions to return to their normal state. In fact during sleep the body engages in a series of postural shifts evidently geared to preventing the musculature seizing-up through disuse. Perhaps then, it is not physical but *mental* rest that is served by sleep.

The brain is the most important organ in the body, working away all day thinking, learning, etc. Should it not have a period of inactivity which ought to be accompanied by a period of unconsciousness or "switch-off"? Unfortunately for this hypothesis, the data from electroencephalography (recording the brain's internal activity by electrodes attached to the scalp) reveal that while there is indeed a significant and very interesting change in the nature of these electrical rhythms during sleep—notably from fast low amplitude to slow high amplitude firing—there is no suggestion that very much *less* is going on. The picture is not one of a run-down of activity, but rather of a shift to activity of a different kind.

So much for the simple commonsense approach—in which, incidentally, dreams are looked on as nothing more than a kind of mistake or error in the system, something to be avoided if a "good night's sleep" is to be had. We do not sleep simply in order to rest (which is not to say, of course, that some rest will not come with sleep).

The Fantastic.

This is the oldest view of all. In many parts of the world it is still the *only* view and while even in our own society large numbers of educated people still believe it, it is really built on an out-of-date fantasy-view of the universe. For this reason we call it "The Fantastic." It has as its main thesis the belief that human beings consist essentially of two distinct parts—the body, which follows the laws of the physical universe; and the mind, soul, or spirit, which is "immaterial." During sleep and in certain other states, this mind or soul may escape the confines of its host body and the normal boundaries of space and time, to roam more or less at will, visiting Australia as easily as crossing a road, and popping into the future for news of the Derby or of the death of a close relation.

Put this way the theory sounds silly rather than just fantastic, but this is not really an unfair representation of a very widely held point of view. The temptation to see sleep as the state of a body with some very important component missing must have been considerable to early philosophers, who, on kicking the body and finding signs of the spirit's return, might then ask the individual where he had been. The reported dream would then be taken as a genuine account of a real experience. For dreams, by this theory, are in part *real* happenings, a hint of the essential spiritual nature of Man and his ability to transcend space and time when the links with the material world are broken.

Support for this point of view comes from the dogma of orthodox religions which say that the soul of man is the true reality, and more enticingly from the strange data of psychical research which nowadays is called parapsychology (J38). The Library of the Society for Psychical Research in Kensington, London, has numerous "authentic" accounts of dream visitations from "dead" relatives, to awful pre-visions of disasters in the future. In the 19th cent., Myers and Gurney pooled masses of these accounts into the enormously interesting volume, *Phantasms of the Living*, which would be one of the most important books ever published if one-twentieth of its contents were true. More recently, the mathematician, J. W. Dunne, claimed in his strange work, *An Experiment with Time*, that dreams definitely provided a mirror into the future, a kind of time-telescope which anyone could learn to operate. Today the beliefs of Myers, Gurney, and Dunne seem less acceptable, and the evidence for telepathy (J51), patiently gathered by Rhine and co-workers two decades ago, now carries less weight than ever among scientists and philosophers.

The cause of this is tied up with the decline in religious belief and the steady advance of scientific knowledge—both developments which make the "Fantastic" view of sleeping and dreaming progressively less acceptable to most people.

The Psychoanalytic.

The contribution of psychoanalytic theory to an understanding of the mind and its complex rules has been greatly overstressed and also greatly underplayed. In fact, the single insight of the unconscious nature of many of our thought processes and their very real power in determining our behaviour is one of the most important concepts in psychology—or even in science for that matter. The psychoanalytic view of dreams has much to commend it, and in simplified form goes as follows: Man is an animal, with animal drives, emotions, and needs. Society, in exchange for protecting him, requires him to obey certain rules many of which conflict drastically with his natura inclinations. These dynamic forces, though they

may be " denied " by the individual at a conscious level, are merely repressed and retain latent psychic power in the inner rooms of the mind. During sleep, with the force of the social censor diminished, these drives and conflicts burst forth in the form of dreams. Mostly the dream itself is then subject to further repression, thus neatly accounting for the odd tendency we have all noticed to forget our dreams almost immediately we experience them.

Now the strength of this theory is inarguable, and the role of the dream in psychotherapy as a guide to the analyst in deciding the patient's *real* as opposed to his declared problems has proved dramatically fruitful in some cases. The real trouble of course is the pretence, lately being abandoned, that this provides a truly comprehensive theory of dreams—a pretence which has led to some awkward questions being asked and some unsatisfactory answers given.

To take a point, most of us have had dreams in which the subject matter seems devoid of any significance in the psychoanalytic sense. To most analysts this kind of remark is anathema—the truth is, they say, that the real nature of the dream is so appalling or of so revolutionary a nature that it cannot even be *dreamt* in its raw form, and must therefore be disguised lest it awake the dreamer. With this escape clause an unshakeable, though highly unsatisfactory, comprehensive theory is possible in which all obvious dreams are obvious, and those which are not are disguised.

This of course means that *any* dream can be interpreted in more or less *any* way to suit the interpreter's particular bias and has robbed the psychoanalytic approach of much of its original power. Although it was exceedingly fashionable at one time, the psychoanalytic theory of dreams is not, and is unlikely to become, a comprehensive one.

Sleep Deprivation.

Though a fair bit was known about the mechanics of sleep—blood pressure falls, temperature falls, etc.—scientists seemed, until quite recently, to be getting nowhere in their quest to find the principal reason for sleep. One of the most persistent lines of approach (and one of the least fruitful as it turned out) was the hunt for specific " toxins " or poisons, supposed to accumulate in the body during the day and requiring sleep to eliminate them. The hypnotoxin, when found, would presumably trigger sleep when a sufficient quantity had built up in the body.

Studies of people and animals deprived of sleep for varying periods made it quite clear that sleep was not just a bad habit, wasteful of time and fraught with danger, but an absolute necessity for sanity and life itself. Most of the higher animals die if deprived of sleep for periods of a week or so, showing, en route, signs of excitability and mania. Humans, if the anecdotal evidence of mediaeval Chinese torture chambers is reliable, die after a period as short as ten days, again showing signs of madness prior to death.

The U.S.A. holds most records for prolonged sleep deprivation, of which one of the best documented is that of Peter Tripp, a 32-year-old disc-jockey who stayed awake for over eight days in the window of a store in Times Square in 1959. Tripp suffered a three-month depression to follow his record, which has since been broken by another disc-jockey, Charles Christensen, of radio station KMEN in California, who managed a stretch under medical supervision of 11 days 13 hours in the summer of 1966. All who have subjected themselves to prolonged sleeplessness are united in stating that the process is very unpleasant and rich in hallucinatory adventure—a fact to bear in mind when considering the meaning of the exciting experiments which first began appearing in psychological journals in the 1950s.

In 1952, Eugene Aserinsky, a Ph.D. student in the Physiology Department of the University of Chicago, noticed that babies spent much of their sleeping time making rhythmic bursts of eye movements, which could clearly be observed through the closed lids. He and the distinguished physiologist, Professor Nathaniel Kleitman, who had been studying sleep and dreams for years, then checked with adult sleepers only to find a similar pattern. This observation suggested an interesting experiment—wake up the sleeper during an eye movement burst and see what he reports. This was carried out with the discovery that people woken during these R.E.M. (rapid eye movement) periods stated that they had been dreaming, while others, woken during non-R.E.M. periods rarely, if ever, reported a dream.

Suddenly scientists had in their possession, for the first time, a behavioural index of dreaming, and all sorts of puzzling questions could be answered. How long did dreams last? How many times in a night did one dream? Did everyone dream? What was the depth of sleep at which dreaming occurred? A series of experiments sorted out these problems, and turned up a number of surprising facts—including that we spend up to 25 per cent of the sleep-period in dreaming.

Further experiments in New York and California, notably by William Dement, were even more sensational. Subjects regularly deprived of the opportunity to dream by being woken at the onset of R.E.M. periods began to show psychological disturbance after a few nights, while a control group, woken for the same number of times and for the same amount of time, but during non-R.E.M. periods, were relatively unaffected. In addition, the dream-deprived subjects, when finally allowed to sleep, instead of dropping into a coma-like state of exhaustion, spent significantly more of the sleep-period than average in dreaming! Evidently we need to dream, and perhaps the true function of sleep was to allow us to do so. But if this was true, just what were dreams that they were so vitally important?

Computer Analogy.

One possible explanation has been offered by a psychologist, Dr. Christopher Evans, and a computer engineer, Mr. E. A. Newman, both of the Division of Computer Science at the National Physical Laboratory. The first version of their theory, " Dreaming—an analogy from computers," was published in the *New Scientist* in 1964.

To understand the idea behind the analogy it is necessary to know a little about some aspects of computer functioning. Computers are advanced calculating machines, controlled by sets of programmes. These programmes are instructions to the computer telling it how to use its brain, as it were, and they greatly extend the potential of the system. One programme, for example, might allow the rapid computation of, say, the average of a long string of numbers; another might deal with the preparation of the salaries and wages of a big firm; a third might control the distribution of goods from a warehouse. Technically speaking all the above tasks, and many more, could be handled with ease by a large computer, and which task it was performing at any one moment would be decided by which programme had been selected.

Now computers are developing at a tremendous pace, becoming more complex and powerful in terms of the range of operations they perform. Even at the present moment a certain amount of time has to be routinely set aside for an important series of operations involving the computers. These operations, which are of particular significance to the theory, involve the act of either clearing the system of old programmes, or modifying and up-dating them, and testing *new* programmes. In other words they ensure that the computer is equipped with the latest and most accurate sets of programmes to allow it to do its job properly.

Now it is an interesting fact that the clearance and up-dating must be done when the computer is, to use a technical term, " off-line," *i.e.*, is uncoupled from any systems that the computer itself is controlling. To give an example, if the computer handles the salary structure of a big firm, then as income tax changes, wages go up, etc., the appropriate programmes have to be modified. If the computer is not " off-line " when these modifications are made and the programme run through, then salaries and wages will be paid at some unsuitable time. Worse, if the computer were controlling the output from some chemical factory, inaccurate or experimental programmes run " on-line " could cause explosions and so on.

It is important to remember that to say a computer is " off-line " does not mean that it is switched off—in fact it may be working like mad, but not coupled to the part of the exterior world it normally controls.

Now the brain is certainly a computer of a special kind, and must be controlled by sets of programmes—though these of course are not fed in by paper or magnetic tape. In addition it is more advanced than most electronic computers because it is *adaptive*, *i.e.*, it continually modifies its own behaviour and capabilities to meet the continually shifting conditions of the world around it. It is with computers such as the brain—and with the increasingly sophisticated man-made devices of the future—that programme revision and clearance processes will be quite vital if the systems are to remain crisply efficient, and more important, are to make the *correct* responses to the changing environment.

In the Evans–Newman analogy, sleep is the state in which the brain-computer is " off-line ", during which time the vast mass of existing programmes are sorted, out-dated ones revised in the light of recent experience, and useless ones or the remnants of modified ones cleared and eliminated. These processes take place for a substantial part of the night, but because the brain is " off-line " and consciousness suppressed we are mostly not aware of them. However, if for some reason our sleep is disturbed or when we wake in the morning, as the conscious mind " comes to " it catches the programme operations at work, and for a moment has no way of knowing whether the events are internal or external in origin. It sets to work, therefore, to try to make sense of the programme or fragments thereof that are being run through, and the result is what we call a dream—though presumably we should call it an *interrupted* dream.

This approach not only helps to explain the importance of the dream process, but also offers some answers to a number of interesting puzzles. For example, a realisation that the logic of the brain's programming and storage system will follow its own internal rules and not necessarily correspond to the logic of the external world, allows one to understand the Alice-in-Wonderland pattern of our dream life. Programmes might, for instance, deal with quite unexpected characteristics of the material stored in the brain—all events concerned with bicycles or spoked wheels might, to take a completely *ad hoc* idea, be the subject of a special programme and *ipso facto* a dream. Faced with such a weird assembly, the conscious mind would struggle to impose a meaningful " story " on the experience, and do the best it could with the material available.

Try checking this idea by examining the content of your next major dream. The trick, by the way, is to concentrate on the *events* within the dream and not be misled by the apparent fatuity of the story. Without too much effort the origin of these events will click into place—this was something from a magazine, that from a conversation, the other from some private train of thoughts of the previous day. Even the most outrageous absurdities will be revealed as muddled or highly-coloured versions of recent experiences.

The computer-programme analogy predicts that the amount of dreaming (and probably sleeping) is a function of the amount of new *material* (*i.e.*, requiring changes in existing programmes) assimilated in the course of the day. Babies therefore, for whom everything is new, need to sleep and dream the most, while old people, who tend to have inefficient information receivers and very static environments, would require far less.

Similarly there should be a rough equation between cerebral complexity in animals and their dream requirements, and this follows pretty well. Chimpanzees require a fair bit of sleep, though not as much as man; while relatively simple-minded creatures, like sheep, need a good deal less. Even further, with insects, who have no complex adaptive computing systems in their " brains ", sleep as we know it doesn't really occur.

The realisation that one of the main functions of sleep is to allow us to dream makes one think again about the role of drugs, as hypnotic agents. Central nervous system depressants, such as barbiturates or alcohol in large doses, might well not only act as soporifics, but also push the sleeper down too deeply for him to dream properly—with unpleasant long-term effects as a backlog of out-dated programmes builds up. It this were pushed too far, the dream mechanisms might well switch desperately into action when the brain was " on-line " (awake), and the result would be hallucinations of an unpleasantly real kind—such as those which prevail in the delirium tremens of alcoholism.

On the other side of the coin is the suggestion that hallucinogenic drugs, such as LSD, might produce their spectacular effects by kicking the dream mechanism into action, again when the computer is " on-line." This would be contrary to the fundamental rules of cerebral mechanics, and while the inner world of the mind would indeed be revealed to the drug-taker, considerable risk would be involved.

Firstly, one would predict a steady deterioration in his ability to distinguish between " inner " and " outer " reality—a condition reminiscent of the schizophrenic state. Secondly, and no less horrifying, is the possibility that " on-line " dreaming would make one " hyper-programmable "—*i.e.*, any stimuli fed in during this time would be incorporated into a major programme and thus trivial events would assume massive significance to the individual concerned. Incidentally, this feeling of having had a revelation out of trivia is commonly reported by LSD-takers. The real risks, it seems, of LSD and similar drugs may not be in the arguable matter of chromosome damage but rather in its effects on one of the brain's most important functions—the dream.

PARKINSON'S DISEASE.

Recent Advances.

An outstanding advance in drug treatment of this disease has been made by the introduction of levodopa (L-dopa) in 1970. The synthesis and eventual commercial production of this substance by the pharmaceutical industry, notably by the Swiss firm, Hoffmann-La Roche, has in itself been a major undertaking and something of a triumph for the research chemists. It is a matter of interesting historical fact that the compound was first isolated in the laboratories of Hoffmann-La Roche as long ago as 1913. At that time the study of the biochemistry of the nervous system and brain was relatively new and the significance of the compound in terms of neuro-physiology could not have been appreciated.

Parkinson's disease is a chronic, disabling disease of the nervous system that is now, in two out of three cases, effectively controlled by levodopa. To understand and appreciate the years of research by physiologists, pathologists, and biochemists into its causes it is necessary to understand something of the disease itself. It is no exaggeration to say that the use of levodopa has in many instances not only transformed the patient's way of life but that of his family or attendants on whom he has had so much to rely for his daily care.

The Disease.

The disease is *paralysis agitans* or *Parkinson's disease*. The first name means, literally, " shaking palsy "; the eponym is the result of the first clearly documented description of the disease by James Parkinson, a London surgeon, in 1817. The disease is an ancient one. Mention of it can be found in 3rd cent. writings but the classical description of the disease and its course remains that of Dr. Parkinson in his published monograph *An Essay on the Shaking Palsy*, a copy of which can be seen in the British Museum.

The name " shaking palsy " is apt, for the cardinal symptoms are *tremor* with *muscle stiffness* which amounts to a paralysis. The onset is very gradual and the full-blown picture of disease may take months or years to develop. The first symptoms may be a feeling of stiffness or weakness in one part of the body—a wrist joint or fingers. A fine, rhythmical tremor of fingers or hands develops, particularly noticeable while the limbs are at rest. Simple movements such as getting up from a sitting position become not only diffi-

cult to carry out, but slow to *start*. The body is held in a rather statuesque manner, with head bent forward, arms and hands held flexed and with a rhythmical tremor of fingers and thumbs characteristic of the movements used in rolling a home-made cigarette.

The difficulty in moving virtually all the muscles leads to a characteristic type of shuffling gait. The feet barely leave the ground and, with the centre of gravity very often over the toes as a result of the bent trunk and forward flexed head and shoulders, the patient tends to totter forward under his own momentum and indeed may actually fall over. His appearance while shuffling thus is as if he were about to break into a little mincing run.

The features become characteristically expressionless, unblinking, and mask-like, with slight drooling at the corners of the mouth. The whole appearance is one of dejection, misery, and immobility. Furthermore, the knowledge that the disease is chronic, disabling, and incurable adds to the general feeling of despair and pessimism in any family unfortunate enough to have an afflicted member. Parkinson's disease affects some 50,000 men and women in Great Britain alone—about one in every thousand. It is a disease of later life, among the age group 50–70, and is twice as common in men as women.

Treatment.

As with any disease of obscure nature and cause, with an inevitably fatal outcome, remedies of every kind have been applied by laymen and doctors alike over the many centuries that the disease has been with us. Parkinson, in his essay mentioned above, was understandably cautious: "until we are better informed respecting the nature of the disease the employment of internal medicine is scarcely warrantable," but that did not stop the purgatives, the arsenic, or the blood letting, favourite empirical remedies of his time.

The first notable advance in treatment was made by the French physician Charcot in the latter part of the 19th cent. He introduced *belladonna*, which had some effect on the excessive salivation and muscle stiffness. Tincture of belladonna was virtually standard treatment by the beginning of the first world war and remained so right up to the 1950s. It was known that the belladonna alkaloids—*atropine* and *hyoscine*—probably exerted their action on those parts of the central nervous system which seemed to be affected in some way by the disease and, gradually, synthetic compounds with similar actions replaced those older remedies. None of these substances did more than ameliorate symptoms—and not particularly effectively at that. Nonetheless, medicine could offer nothing better.

From post-mortem and other studies it had gradually become clear that the seat of the mischief in this baffling disease was in a part of the brain, an area concerned with the maintenance of many bodily activities of which we are never truly aware until something goes amiss. One of these activities concerns the "tone" of musculature generally and the preservation of the right balance between muscles which have opposing actions. It is obviously necessary, when bending the forearm for instance, for the muscles whose action is to straighten the elbow, to *relax* while flexor muscles do their work—or no movement would take place. And when the arm is at rest it is obviously necessary for any tendency for one set of muscles to overcome the other to be corrected—or the arm would not be still. All these co-ordinative activities are controlled below the level of consciousness in an area of the brain which contains the nerve-cell computing centres—the *basal ganglia*. The particular area affected in Parkinson's disease is known as the *corpus striatum*. (The early neuro-anatomists could only describe these different areas of the brain by their naked-eye appearance, only guessing at their probable function.) It is beyond the scope of this article to go further into the detailed pathological changes in those areas of the brain which have been described in subjects dying of the disease. It is sufficient to mention that until the later 1950s the changes described—essentially of loss of nerve cells and degeneration of axons, which are the connecting fibres of such cells—were attributed solely to some type of senile degenerative process associated with age and possibly mediated by arterio-sclerotic types of vascular degeneration in particular (such as atheroma, *see* P30(1)). The incidence of the disease is greatest by far in the 50–70-year age group and that fact gave credence to such views.

However, the general impetus given to medical research by the second world war led in particular to concentrated effort in the field of biochemistry, particularly the biochemistry of "transmitter substances" or hormones. It had been known for a very long time that the opposing states of general bodily physiology—on the one hand, the alert, "fight or flight" state, with blood-flow diverted to muscles, quickened heart beat, raised blood pressure, dilated pupils, and general pallor, and on the other, the relaxed drowsy state of the contented post-prandial dozer, with slowed heart rate, lowered blood pressure, small pupils, and flushed appearance—are basically controlled by the output of adrenalin and acetylcholine respectively. These two states—the "sympathetic" and "parasympathetic"—are mediated and maintained by the actions of the *peripheral* nervous system but are under the master control of the *central* nervous system—the brain and spinal cord.

The idea gained ground that the symptoms of Parkinson's disease—which are predominantly those of parasympathetic, or (acetyl)*cholinergic* activity—might be the result of an essentially *chemical* imbalance between two opposing substances in brain tissue itself. A discovery of major importance was made by three German scientists—Hornykiewicz and his colleagues—in 1961. These workers found that the adrenalin-like neuro-transmitter compound, *dopamine*, was grossly lacking in the basal ganglia of patients with Parkinson's disease. Dopamine and acetylcholine have the same relationship in the *central* nervous system as adrenaline and acetylcholine have in the *peripheral* system. If dopamine concentrations fall, then cholinergic activity predominates—and this is just what seems to be happening in this disease. Belladonna and its alkaloids exert their action by antagonising acetylcholine—and hence their use in patients with Parkinson's disease went some way towards restoring the balance and relieving the symptoms.

The *anticholinergic* drugs (now largely synthetic compounds with belladonna-like actions) certainly gave *some* relief but the dose required to do so often meant that side-effects—excessive drying of salivary and bronchial secretions—made life more uncomfortable for the sufferer than his untreated disease. Following on the discovery that dopamine levels in the brain were sub-normal in the disease attempts were made to correct the situation by giving patients dopamine by mouth. Unfortunately dopamine, while readily absorbed by the body, does not get into the brain across the "blood-brain barrier," a physiological brain-protecting mechanism that blocks the entry of many drugs and, indeed, some physiological substances as well.

Dopamine, like many other "chemical messenger" substances in the body, is normally produced on site, as it were, from an inactive precursor. This is *dihydroxyphenylalanine* or "DOPA" which is derived from one of the amino acids, those chemical units which form the complicated molecules of animal and vegetable protein. DOPA crosses the blood-brain barrier readily; dopamine, as has been pointed out, does not. DOPA is readily converted to dopamine in the brain and in early experiments in man in 1962 a Canadian physician, Barbeau, produced quite dramatic but short-lived improvement in Parkinsonian patients by giving small doses of DOPA by mouth. The improvement was mainly in paralysis—the difficulty in *starting* and *maintaining* muscle movement—and was better than had up to then been obtained either with anti-cholinergic drugs or with the highly specialised and sophisticated techniques in brain surgery which had been developed gradually since the early 1950s.

The early attempts to restore dopamine levels in the basal ganglia of the brain by oral DOPA were frustrated by the fact that if more than transient improvement were to be made, much larger doses had to be given. Inevitably, there

were unpleasant side-effects. At that time, too, DOPA was difficult and expensive to produce and mainly only available in what the chemists call the *racemic* form. Racemic compounds are mixtures of two *chemically* identical substances whose molecules differ in their spatial arrangements of atoms. One is, in effect, the *mirror image* of the other. Physical chemists are able to distinguish one form from the other by special techniques which enable them to "look" at molecules three-dimensionally. In some examples, polarised light can be used to distinguish one from its "mirror pair" by its ability to rotate the plane of polarised light to the left or to the right when it is passed through a solution. This is true of the "D" and "L" forms of DOPA. (*D*extro and *L*aevo.)

It was soon realised that the "D" form is not only virtually inactive as a dopamine precursor (it is a form not found naturally in the body) but is toxic. The "L" form, however, seems to be the natural precursor, readily absorbed into brain tissue and much less likely to produce toxic reactions. Furthermore, as equal parts of the "D" and "L" forms are present in the racemic mixture the same effects could be produced with half the dose of substance when the "L" form was used on its own.

Unfortunately, the "L" form proved difficult to synthesise or separate from the racemic form. Supplies were scarce and costly in comparison to the "DL" form and the early trials, because dosage was kept on the low side, were largely disappointing. The breakthrough came in 1967 when theoretical considerations led to the pioneering use of much larger doses than had been attempted heretofore by Cotzias and his colleagues in the U.S.A. They were forced to use DL DOPA, the "L" form being in extremely short supply and very costly, but built up the dose given to their patients by slow, carefully monitored steps to the maximum that could be tolerated. It was a case of "titrating" the patient to achieve maximum therapeutic effect with the minimum of unwanted side-effects. It was found to be the only way to get to a lasting, effective dose without upsetting the patient in other ways. In some instances as much as 16 grams a day had to be given.

Nevertheless, in spite of careful administration and the slow build-up of dose-levels, there were many side-effects which, if nothing else, were disagreeable to the patient. Not only that, but one patient's blood-cell forming system was affected—a condition known as granulocytopenia—and this represents a potentially serious hazard.

By this time, as a result of research effort within the pharmaceutical industry, the effective and less toxic "L" form of DOPA became less expensive to produce and relatively less scarce than before. Cotzias and his co-workers undertook a further trial in 1969 using "L" dopa alone. Again, maximum effect was achieved by working up to an optimal dosage; in that trial there were no serious, or potentially serious, side-effects and the solely "troublesome" ones—nausea, vomiting, abdominal pain and the like—were found to be dose-dependent. In other words, they could be avoided by reducing the quantity of "L" dopa used. 28 patients were treated in this trial—and all improved, 20 of them markedly or dramatically.

It will be recalled that the dominant and most distressing features of the disease are the stiffness, the slowness, the difficulty in initiating movements and the tremor. The first three are known to the physician as rigidity, bradykinesia, and akinesia and it is on these that levodopa has its maximum therapeutic effect. *Tremor* may respond after prolonged treatment in some patients, but not all. The effect on the patient when he finds he can get up from his chair or his bed *unaided*, when he begins to *walk* instead of shuffle, when he can cough healthily to clear his throat, when his handkerchief can be kept in his breast pocket instead of being held constantly to drooling mouth, when he can feed like others and feel his face break into a smile, is dramatic. And if he has been somewhat dysphonic (having difficulty in speaking, through stiffness of jaw and tongue muscles), as many patients are, the return of normal or near-normal speech is perhaps the final booster to a morale that has often sunk to its lowest level. His renewed optimism spreads to family and friends. Return to work becomes a reality and restoration of independence naturally follows.

It must be mentioned that some patients fail to respond at all, perhaps something less than one in three. There is as yet no means of predicting response to levodopa. But it should not be forgotten that, although levodopa now tops the list of symptomatic remedies for Parkinson's disease, the others remain—the anticholinergics, amantadine, and, mentioned briefly above, stereotaxic surgery. And most patients can expect some response to one or other of these.

There is no doubt that levodopa is the most powerful of the new drugs available in the anti-Parkinson armamentarium. In the three years since its introduction it has been given to many thousands of patients throughout the world, the majority of whom have benefited in the ways indicated in this article. But the *cause* of the disease is still unknown and levodopa does no more and no less than correct the biochemical abnormality which seems to be responsible for the symptoms.

It is possible now to make some assessment of the long-term effects of continued administration of the drug. One fact is clear—levodopa does nothing to slow down let alone halt the underlying disease process even though, for the majority, it makes the manifestations a little easier to bear. Nevertheless, it is safe treatment and has no unpleasant side-effects which cannot be minimised by careful adjustment of the dose.

Fears that the continued use of levodopa would upset the body's delicate endocrine balance to such an extent that diabetes mellitus (P39(2)) or acromegaly (P43(2)) might begin to appear during the necessarily prolonged treatment have not been confirmed in practice. On theoretical and experimental grounds such complications could be anticipated.

Transient "escapes" from the beneficial effects of levodopa have been noted in some patients who have had treatment for more than a year. Known as "on–off phenomena", these episodes consist of a rapid and unheralded deterioration in the patient's condition with a return of rigidity and akinesia which may last only an hour or persist for half a day. Relief returns spontaneously without any adjustment of dosage.

It is common experience that therapeutic advances in the treatment of chronic, disabling diseases are more likely to be palliative than provide us with a cure. Levodopa is no exception. But palliation not only gives the sufferer relief from distressing symptoms but also buys time for the fundamental researcher. There is no question that levodopa is a significant step forward and must in the long term add considerably to our understanding of the disease.

CHILD ABUSE.

The dramatic term "battered child" was first used twelve years ago to draw attention to a problem that had caused increasing concern in the U.S.A. Initially, it referred to children who had suffered severe physical violence but later it was used in connection with other forms of child abuse. A "battered child" has recently been defined as one who has received non-accidental physical injury (or injuries) as a result of acts (or omissions) on the part of his parents or guardians.

Children have been abused throughout history but most agencies and legislation to protect them have only developed in the past hundred years. Previously the welfare of the child was regarded solely as the concern of the parents. There is little exact information about the nature and extent of the problem in the past. Consequently it is not certain if child abuse is now more frequent than it was or whether it is simply being recognised more often. It is clear, however, that the "battered baby syndrome" is now common in Great Britain and the United States and it has been estimated to affect six out of every thousand children born.

I. The Consequences of Physical Violence.

1. Bone Injury.

Injuries resulting from neglect or ignorance and those due to non-accidental attack are often indistinguishable. Nevertheless some children show bruising or changes on X-ray that are characteristic of certain types of assault. Radiological examination is imperative when there is suspicion or inconclusive evidence of non-accidental injury. It has been aptly stated that "the bones tell a story the child is too young or too frightened to tell."

Current interest in the problem of the battered child was initiated by Dr. J. Caffey, an American radiologist, who recorded that a number of children with sub-dural haemorrhage (collections of blood underneath a lining membrane of the brain) had multiple fractures of their bones. Fractures are common in abused children and battering is said to account for roughly a quarter of all fractures seen in the first two years of life. X-rays of infants who have been repeatedly assaulted sometimes show fractures in different stages of healing. In addition, the periosteum, a fibrous membrane covering bones, can be injured, but this may not become apparent until a few weeks after the battering episode.

Fractures of the skull and long bones are encountered in children who have suffered direct violence from an enraged adult and in those who have been thrown against walls or down stairs. Other children sustain bone injuries as the result of being vigorously shaken. In these children the epiphysis, or growth centre, normally connected to the shaft of the bone by cartilage, is separated. X-rays may immediately reveal displacement of the epiphysis or, in some cases, fragmentation of the part of the bone joined to it, but in others it is not until healing begins to occur that characteristic radiological changes are visible. Additional damage may result from vigorous shaking because its centrifugal effect may cause haemorrhages into the brain and eyes.

Although fractures usually indicate that a child has been subject to undesirable violence, whether it be accidental or deliberate, it is not necessarily so in all cases. A few children have abnormally fragile bones due to a familial disorder called Osteogenesis Imperfecta, others may have fractures as a consequence of leukaemia or other malignant diseases. Periosteal reactions similar to those produced by trauma may occur in conditions such as scurvy and congenital syphilis and tests to exclude them are required. In all cases the greatest care has to be taken in interpretation of the findings so that false accusations are not made and inappropriate action taken.

2. Soft Tissue Injury.

Most children get bruises, cuts, or abrasions during normal play. Ill-treatment is inferred if they are excessive in degree, inconsistent with the history of their occurrence, or characteristic of injury by certain defined implements. In many cases, however, it is impossible to be certain about their cause.

Injuries to the skin are called abrasions and they reflect the nature and extent of violence more accurately than do bruises. Among the most informative marks are those due to cord around the ankles or wrists used to tie children into cots and those due to belt buckles which often cause distinctive abrasions on the buttocks of severely punished children. Repair of the injured skin takes place within a few days but distinctive pigmentation may persist for a considerable time.

Bruises occur when small blood vessels under the skin are ruptured and they usually result from blows with the fist or from pressure from the fingers where the child has been firmly held. Occasionally children are bruised by straps, canes, or other blunt objects. The extent of bruises depends not only upon the amount of force used but also upon the laxity of tissues in the parts affected. They do not, therefore, always give a clear indication of the degree or nature of the blow but some forms of bruise are frequently seen on abused children. Swinging blows from a parent's fist usually cause bruising to the left side of the face and "finger print" bruises are characteristically seen at the side of the mouth when it has been forced open, or on the upper arms or trunk when the child has been shaken. In all cases of significant bruising, haematological examinations need to be done to ensure that there is not a disorder of the blood or capillaries.

3. Visceral Injury.

Injuries to organs within the abdomen or chest due to deliberate assault usually, though not always, present as medical emergencies. In the absence of prompt and expert treatment many would result in death. They are caused by heavy blows such as kicks to the abdomen or chest and some children who show few external signs may have been seriously injured.

Most parts of the intestine are mobile within the abdomen and escape injury, but its wall can be torn. The upper part of the small intestine (the duodenum) and the first part of the large intestine (the caecum) are more firmly fixed than the rest and are, therefore, more exposed to injury. Rupture of the intestine causes sudden severe abdominal pain and shock as does bleeding from lacerations of the liver, the spleen, or the kidneys. It is possible, however, for haemorrhage to occur behind the peritoneal lining of the abdomen and this may not be immediately evident.

Chest injuries in children are relatively uncommon because the ribs are very elastic. Bruising of the surface of the lungs may occur but these injuries are unlikely to cause marked symptoms unless the lung tissue is torn as the result of very severe blows. The heart is rarely injured but bleeding into the part between the two lungs called the mediastinum, is recorded.

II. The Consequences of Neglect or Passive Abuse.

In contrast to the *commission* of physical violence, neglect implies *omission* of adequate care or supervision. Often it is unintentional but in some cases neglect is deliberate and the quality of the act may be difficult to distinguish from that of wilful assault. It usually involves several aspects of child care at once but for purposes of description these will be considered separately.

1. Lack of Cleanliness.

All normal children get dirty and in situations of social distress normal efforts may not be made to clean them at the end of the day. There is, however, a difference between recent dirtiness and that caused by neglect of washing over long periods of time. In the latter, the skin is ingrained with dirt and there are often accumulations of dark greasy material under the nails, between the toes, and in the groins. There is a characteristic offensive smell and the child may have infections of the skin as well as infestations with fleas, lice, or mites. The hair often feels dry, lacks lustre, and the scalp is dirty. Infants may have a crust of greasy scales over the scalp which becomes grey with dirt and the underlying skin occasionally becomes inflamed.

Children neglected in this way are at greater risk of contracting dysentery, gastro-enteritis, and other conditions spread by contamination of the hands. It is reasonable to presume that repeated exposure to infections has a damaging effect on physique notwithstanding that the majority of episodes of illness are not severe. In addition, psychological trauma (damage) is probable in that the general offensiveness of these children can be such that their fellows tend to avoid association with them.

2. Lack of Warmth.

The clothing of neglected children is often dirty, offensive, and in a poor state of repair. Occasionally they are turned out inappropriately and are unhappy because of the contrast with their fellows. Gross inadequacy of the amount of clothing is not usual though footwear and outer garments are frequently unsuited to wet weather. Bedding is more often insufficient for warmth and some neglected children spend long, miserable sleepless nights with obvious ill-effect upon their well-being.

3. Lack of Food.

One meal is sometimes withheld as a punishment but wilful deprivation of food over a long period is uncommon. Serious undernutrition is most likely to occur in young children of parents who are mentally ill or who use their income, whether from employment or Social Security, to buy alcohol or for gambling. Undernutrition is usually one of several facets of neglect evident at the same time. When such children are provided with adequate food and care their subcutaneous tissues often fill out quickly and their growth increases remarkably.

Failure to thrive is associated not only with other forms of passive abuse but also with physical injury. In the N.S.P.C.C. study of 78 battered children, nine had failed to progress satisfactorily and all except one had fractures.

4. Failure to Protect from Injury.

After the first year accidents are the principal cause of child death and those in the toddler age groups are particularly vulnerable. Children who do not receive adequate care are at a substantially greater risk of injury on the roads and in the home.

Burns and scalds are among the most common accidents and neglected children frequently have characteristic scars of old burns. A number are due to failure of the parents to use fireguards even though they are relatively cheap and some Local Authorities make free loans of them to needy families. Serious burns often result from the use of night attire that is not flame-proof, especially night gowns used by young girls. Children are frequently scalded by pulling boiling liquids on to themselves and this is particularly likely to happen in families where cooking has to be done on open fires because gas and electricity are disconnected. Burns are sometimes wilfully inflicted by parents as with the circular cigarette burns sometimes seen on abused children.

5. Failure to Obtain Medical Treatment.

Many neglected children have sores which become infected because of lack of normal cleanliness and the provision of suitable dressings. Infections of the ears, nose and throat are common and dental and ophthalmic treatment often go by default. Neglect is usually most apparent in treatment of long-standing conditions that do not pose any immediate threat to life but sudden deaths in the first year are, nevertheless, more numerous in this group of children.

6. Failure to Give Security and Affection.

The most important rôle of parents with regard to their children is to give love and attention, and failure in this respect often, though not always, accompanies physical neglect. It may occur because of the parents' inability to become attached to the child, or it may be incidental to social insecurity, marital disharmony, or illness. A characteristic of many battering parents is that they are hypercritical, demanding, and unable to give affection.

Some parents may be responsible for acts calculated to frighten; for example, they may lock the child in a dark cellar as a punishment. Others may evoke fear in their children because of repeated blows or threats of violence. Such children are often very anxious in the presence of adults in general and of their parents in particular. The damage caused by such events depends upon the basic personality of the child and the extent to which substitute relationships are possible with the other parent, siblings, extended family, or friends.

III. Causes of Child Abuse.

Each incident of abuse has its own peculiar underlying causes that are essentially complex. Extrinsic social factors and the behaviour of the child play some part but of basic importance is the mental state of the parents and the way they are able to interact with their child and their environment.

1. Parents Who May Abuse.

Baby battering occurs in families of all social classes and it is not wholly confined to parents of any one psychological type. Only about 5% of physically abused children have mothers or fathers who suffer from psychotic illness but the importance of recognising them makes psychiatric examination of abusing parents important. In most cases there is no intention to injure but occasionally those with a depressive illness try to kill their children prior to suicide. The families of a few people with schizophrenia may be at risk of injury or death as a result of delusions suffered by their parents. Loss of contact with reality more frequently leads to a deprivation of acceptable standards of child care rather than to violence. A further 5% of abusing parents are aggressive psychopaths, that is, people who show persistently irresponsible, aggressive behaviour. Battering of children is only incidental to their life pattern which includes threats to and assault on their wives, neighbours, and others.

Most parents responsible for injuries do not suffer from recognisable mental illness and the damage that they do arises from their intent to make their child behave. Many do not think that their actions have been wrong and resent interference. They frequently give a history of separation from or unhappy childhood experiences with their own parents. It has been suggested that they use the child to satisfy their own emotional needs and disregard those of the child. There is, therefore, a lack of real mothering in that, although there may be satisfactory material care, the child is deprived of a warm loving relationship. Both violent and neglecting parents are critical and demanding of their children; the difference between the two appears to be that when the child's response is inadequate to their needs, one reacts by punishing and the other by abandonment of material care.

There is no direct relationship between abuse and parental intelligence. Since the intention is to punish rather than to injure, it is reasonable to presume that more severe damage will be done by parents with diminished understanding. Similarly, the effects of physical neglect are generally most marked on the children of the unintelligent because it usually occurs against a background of poverty. An indirect relationship is therefore probable, but low intelligence of itself is not a fundamentally important cause of child abuse.

Social isolation is important in this context. It is significant that, in this country, the majority of known acts of cruelty occur in large towns. They seem to have become more prevalent at a time coincident with a housing and industrial situation leading to mobility and separation of families. Abusing parents frequently have difficulty in making satisfactory interpersonal relationships and are often withdrawn from society. The child of such parents in city areas does not, therefore, benefit from the protective sanction that would occur in closely knit smaller communities.

2. Children Who May be Abused.

Some children are more likely to get battered than others. The younger the child, the greater the risk of its occurrence. More than half the children in the N.S.P.C.C. study were less than a year old. Premature or low birth-weight babies have twice the expected incidence of inflicted injury. This may be due to unavoidable separation following birth impairing the normal procedures of attachment of the mother to her child. The same considerations apply to adopted children.

The actual attributes of children are less important than how they are seen by their parents. Parental expectations are often unrealistic but if the child is able to meet them he is unlikely to get battered. Although some abused children are less satisfying than others because of mental subnormality or recurrent illness, most are normal before battering occurs.

3. Social Factors in Battering.

Abuse may occur in any social or ethnic group and the crisis needed to provoke it may be

extremely trivial. Nevertheless, stress and isolation of young families are very important contributory causes. In the N.S.P.C.C. study mentioned previously, 28% of children were not living with both natural parents. Of 71 families whose work situations were recorded, 41% received no earned income at the time of the battering incident so financial problems and debts or rent arrears were relatively common. Housing problems affected 35% of the families and changes of accommodation seemed to be used by some to escape from outside pressures. Abusing parents are characterised by a failure to get on with neighbours, relatives or child welfare agencies and they tend to be social isolates.

IV. Prevention of Child Abuse.

The problem of abuse is that of identifying and providing adequate care for parents who may, under certain circumstances, batter their children. Many of them are recognisable in the prenatal period but effective action is difficult to organise at this stage. Nevertheless, it has to be undertaken early to prevent the irreversible injuries suffered by many children.

Lack of kindness, warmth, and affection in their childhood is a basic cause of parents being able to abuse their children. A penal approach to the problem is therefore unlikely to be helpful in most cases. Attempts have been made, notably in Colorado, U.S.A., to provide "parent-aides" who are lay-workers prepared to commit themselves to the support of these deprived parents. They try to provide a non-directive and non-critical mothering experience for the parents and hope to establish a relationship which gives mothers the confidence to call for help in times of crisis. The personal dedication required of lay and professional workers in this field is very great as are the administrative problems so that there are few adequate programmes for dealing with child abuse in Britain at present.

After abuse has occurred, even though it may not be serious, admission to hospital or to a safe place away from the home is necessary. Legal proceedings may be required to provide suitable protection for the child. Children who have been once injured are very likely to receive further assault. Indeed one of the major problems is to decide if and when it is safe to return such children to their homes. Brothers and sisters can be in equal danger and action may be needed in order to protect them. Because of the medical, social and legal complexities of the situations that can rise, it it desirable that abuse should be dealt with by experienced personnel. Teams are presently being formed for this purpose in many parts of the United Kingdom.

VITAMIN C AND THE COMMON COLD

In this and earlier editions of our medical section, reference is made to the vogue for prophylactic treatment of colds with massive doses of vitamin C (P10(2)). Recently laymen and scientists alike have re-focused their attentions on the issue as a result of the publication of a popular paper-back *Vitamin C and the Common Cold*, W. H. Freeman & Co., California and Reading, 1970, first in the USA and later in this country, authoritatively written by a Nobel prizewinner whose name has now become almost a household word—Linus Pauling.

In his book Pauling sets out the results of critical examination of the evidence for an effect of Vitamin C on the prevention and treatment of the common cold from clinical trials carried out in many parts of the world since the middle 1940s. He then adds his own personal experience and those of some of his friends and concludes that there is enough positive evidence to recommend treating communities all over the world with large doses in the hope of eventually eradicating the disease completely. At the same time he freely admits that this would take decades as he still does not know how effective his recommendations would be.

It is beyond the scope of this article to include a critical review of Pauling's hypothesis and the conclusions he has come to—others have undertaken that task—but it may be useful for the reader to have some of the salient facts assembled for him from which he may draw his own conclusions or conduct his own personal investigation of the claim.

There is an enormous amount of chemical and physiological information on vitamin C (ascorbic acid) in the scientific literature about which there is little or no dispute. Man, together with a few other animal species (the guinea pig and the fruit-eating bat, for example), has somewhere along the evolutionary road lost his capacity for synthesising ascorbic acid from his food and needs a constant supply of the ready-made material (present, fortunately, in many of our foods) in his daily diet. If he doesn't get enough of it he will develop *scurvy* (P43(1)). It has been shown in experiments on volunteers that as little as 10 mg of ascorbic acid taken daily will *prevent* scurvy although amounts somewhat in excess of that figure are needed to bring about a rapid cure. But that is the *minimum* amount required; individuals vary greatly in their nutritional requirements and one cannot quote a minimum amount that will apply to all. To be on the safe side, therefore, governments (through their appropriate health and welfare departments) publish in their tables of "recommended daily allowances" figures for vitamin C (*inter alia*) in excess of that minimum figure. Currently it is 30 mg/day (UK) and 50 mg/day (USA). These amounts allow for individual variation as well as a broad safety margin and are considered to be adequate to maintain normal health.

The rest of the animal world still able to make its own ascorbic acid does so *ad libitum*. Their tissues—blood, white cells, adrenal glands, and so on—are in a state of saturation as far as ascorbic acid is concerned. Feed them with more—and they do not retain it. It is argued that man (and the guinea pig and the fruit-eating bat) should take in sufficient vitamin C to maintain *his* tissues in a state of saturation. How much would that be? Again, individuals vary, but from measurements made in healthy volunteers it would appear that doses of the order of at least 100 mg/day would be required to keep tissues replete. It must be remembered, too, that the body "pool" of vitamin C can readily be reduced by physical stress, by smoking, by drinking alcohol and by acute or chronic illness; there are times, therefore, when intakes of even greater amounts can be justified. In such situations 500 mg/day or more may be needed to keep a "saturation" level. Pauling has estimated that the optimum amount of vitamin C—*i.e.*, the amount needed to keep one in "the best of health"—ranges from 250 mg to as much as 10 grammes a day. Not all would agree with him by any means—but that is the sort of dose he takes himself.

Vitamin C has many functions in the body and *scurvy* is the direct result of an insufficient supply. It has been known for a long time that the white blood cells are involved in coping with infection and that their phagocytic (that is, bacteria destroying) activity is related to their vitamin C content. The common cold, however, is the result of infection by a virus or viruses (some 40-odd varieties are known) and the phagocytic activity of our white cells has little or no part to play in combating virus infections. Nevertheless there are two facts which lend support to the growing belief that vitamin C has a part to play in preventing or alleviating the cold. One is that *interferon* (L63), an anti-viral protein produced in body cells in response to viral invasion, may need ascorbic acid for its synthesis or activity. The other is that many of the unpleasant symptoms of the cold are due to secondary infection by bacteria and in that situation the phagocytic properties of the

ascorbic acid-laden white cell have an obvious part to play.

In practice, do large doses of ascorbic acid work? There have been many attempts during the last 30 years or so to plan and carry out experiments—clinical trials—in an attempt to answer what seems to be just a simple question: "Does vitamin C prevent or alleviate the common cold and, if so, in what sort of dose?" But trials of this kind are in fact fraught with difficulties, not the least of which is the problem of defining the cold in such a way that we can recognise it in the trial subjects and that others can agree that our definition and our recognition are correct. The common cold is not a serious condition and, obviously, one has to depend entirely on subjective evidence for diagnosis; only in boarding schools and other residential establishments where there may be a doctor carrying out a daily "sick parade" is it possible to obtain objective evidence that a subject's symptoms and signs fall into the agreed definition of a cold.

Clinical trials must also be *controlled*—that is to say we must compare the incidence of colds in a group taking vitamin C with the incidence in another group taking something else, or nothing at all. Usually it is better to have a control group taking a tablet which looks and tastes like the vitamin; if neither the doctors in charge of the trial nor the subjects taking part *know* who is taking what, then the trial is "double-blind". In that way, there is no chance of observer or subject bias. Furthermore, the two groups should be matched in terms of age, sex, and environment, be exposed to the same risks of catching cold and be equally susceptible to those risks. All these criteria should ideally be met if results are to have any validity; many trials have failed on one or other.

If vitamin C had the same striking effect on colds as does morphine on pain or aspirin on rheumatic fever there would be no need for such controlled experiments. The effect, if it exists, is probably small (although, remember, the problem is very large) and will not show up unless a trial is carried out with large numbers of subjects under the rigid conditions mentioned above. But, as Pauling has pointed out, in terms of economic gain, even a 25% effect would be worthwhile. On a nation-wide scale, 1 in 4 fewer days off work for colds or minor upper respiratory illness would be a tremendous economic advantage.

At the time Pauling published his book, there had been few controlled trials that would stand up to rigid statistical analysis. Those that did showed at best a trend towards a positive result in favour of vitamin C and an honestly objective assessment would be that the case for vitamin C was simply "not proven". There nevertheless remained a core of opinion, professional and lay, that large doses of the vitamin do have *some* effect in *some* people.

In the autumn of 1972 a group of Canadian doctors working in Toronto published the results of a large-scale, double-blind controlled trial; they studied the effect of one gramme (1000 mg) of vitamin C compared with a dummy tablet in a group of just over 800 people during the preceding winter months. All in the group normally experienced at least one cold each winter. Vitamin C and dummy tablets were randomly allocated and, as has been explained, neither doctors nor volunteers knew which was which nor who was having what—*i.e.*, the trial was double-blind.

Each subject kept a daily health record and noted symptoms on that record when they appeared. If a cold developed the instructions were to increase the intake of tablets to four grammes a day while symptoms lasted. One thousand people enrolled for the trial, just over eight hundred completed it. When the cards were analysed and the random allocation code "broken" it was found that 407 had been taking vitamin C and 411 the dummy tablet. The results, quoted from the author's own summary, were as follows:

"It was found that in terms of the average number of colds and days of sickness per subject the vitamin group experienced less illness than the placebo group (that is, the group taking the dummy tablet), but the differences were smaller than have been claimed and were statistically not significant. However, there was a statistically significant difference ($P < 0.05$) between the two groups in the number of subjects who remained free of illness throughout the study period. Furthermore the subjects receiving the vitamin experienced approximately 30% fewer total days of disability (confined to the house or off work) than those receiving the placebo, and this difference was statistically highly significant ($P < 0.001$). The reduction in disability appeared to be due to a lower incidence of constitutional symptoms such as chills and severe malaise, and was seen in all types of illness, including those which did not involve the upper respiratory tract."

Some explanation of the terms "statistically significant" and "$P < 0.001$" may be helpful to the reader. The probability that observed differences in the number and quality of events occurring in time in two "samples" from a given population are due to chance can be calculated mathematically. If the observed difference is one that would be likely to occur only *once* in a series of 20 trials (or more) the difference is regarded by statisticians as "significant". In other words we might fairly consider it a consequence of the difference in treatment (with a one in 20 chance of being wrong). If the mathematical tests show the difference to be likely to occur by chance only once in a hundred or once in a thousand trials then we can consider it to be "very significant" or "highly significant" respectively (with one in a hundred or one in a thousand chance of being wrong). The "P" values given in brackets in the summary are the probabilities that the results are due to chance—<0·001 being another way of saying "less than one in a thousand".

The Canadian study was carefully planned and painstakingly carried out by a group who publicly confessed to be "sceptical of Pauling's claims." Their results are of considerable practical and theoretical importance. Practical, because they effectively demonstrate a safe and simple method of reducing time lost through minor indisposition in industry; theoretical, because here is strong evidence that the present recommendation for a vitamin C intake to maintain "normal health and fitness" may need drastic revision. The results lend support to the extreme views expressed by Pauling and others in his admittedly controversial book and have already attracted world-wide interest. Because of the largely unexpected result (the highly significant effect on the total days of disability) the Canadians intend to repeat their study in other groups. Indeed it is probable that others will set up similar studies in this country and in Europe; confirmation of their results is urgently needed.

Apart from the interesting Canadian results it is clear that the trial—and indeed many others which have not proved so definitive—demonstrates that vitamin C can be taken with impunity over long periods of time by normal healthy people in doses which amount to anything from 20 to 200 times the official "recommended daily allowances". The substance, either in its natural or synthetic form, appears to be virtually harmless. Should further results from other trials confirm the Canadian findings then indeed we shall have made a real advance in the conquest of a common problem.

SUDDEN INFANT DEATH.

Editor's Note to Readers.

This article discusses an important and unpleasant topic. As with all other parts of the Medical Section it is written by an expert in the strong hope that readers will be interested and even helped by it. It will have failed if parents are made unduly anxious. Constant worry and anxiety in parents of normal children can seriously harm the development of their children's personality; so that if anyone feels as worried as this they should get their fears sorted out rather than trying to live with them, by talking freely with their doctor or health visitor.

Each year a surprising number of infants die unexpectedly. In most cases death occurs at home and often during the night while the parents are asleep, hence it is sometimes called "cot death." Examination of such babies reveals a well-defined cause such as an acute infection or a major congenital defect in about 30 per cent of the

children but in the other 70 per cent no abnormality sufficient to account for death is found and the matter is therefore a puzzle and an important one at that. They are said to die from "Sudden Infant Death Syndrome" and it is the most common mode of death in infants after the first week of life.

How Often Does it Happen?

A preponderance of sudden death in infants between one week and one year of age is to be found in the mortality statistics of many developed nations. Its precise incidence is uncertain and cannot be determined because of differences in autopsy technique and of death certification but surveys suggest that in the United Kingdom between one and two thousand babies die unexpectedly each year from an unknown cause. As many as one in every four hundred babies born may be affected.

There is a striking uniformity about the age at which Sudden Infant Death Syndrome occurs. It is rare in the first three weeks of life but rises sharply to a peak between the ages of two and four months. Subsequently it falls rapidly so that sudden deaths after six months are unusual though there is a gradual tailing off up to the age of two years. The average age of death in one study was 3·9 months and this approximates to the general experience in Europe and North America.

Most of the deaths occur between November and April and peaks have been shown to correspond to community outbreaks of viral illnesses, especially Influenza. In the families of children who have died, throat infections are more common than in the general population and this implies that some of the deaths are due to acute respiratory disease.

There are several associated factors, but these in themselves do not actually *cause* Sudden Infant Death. Prominent among them is low birth weight due to prematurity. The proportion of these babies who die unexpectedly is two or more times greater than that of full-term infants. It is curious that they tend to die at about the same time that they might have died had they not been born prematurely. Artificial feeding with cow's milk preparations is another concomitant factor and one which has some practical significance. It is unusual, although not completely unknown, for breast-fed infants to die in this way and, if continued for several months, breast feeding is the most effective available preventive measure (as it is for many other ills of babyhood).

Adverse social circumstances such as poverty, illegitimacy and overcrowding are often, though not invariably, associated with Sudden Infant Death Syndrome. It is relatively more common in the children of large families and those born to semi-skilled and unskilled workers. The parents tend to be young, are more likely to be below average in intelligence and few of them take their children to Infant Welfare clinics. In the U.S.A. there are more cases among coloured people and this reflects its increased liability to occur in socially deprived circumstances. Despite this strong correlation with adversity, Sudden Infant Death Syndrome sometimes happens in the families of prosperous, intelligent parents and occasionally while infants are under expert supervision in hospital.

Some families lose more than one child, though the chance of successive children being affected is not very great. Twins have been reported to die unexpectedly about the same time as each other but there is no evidence of any inherited predisposition to sudden infant death and consanguinity is not a factor.

Course of Events.

Most infants are considered to be in reasonably good health in the period immediately before death. Approximately one half to two thirds of them have mild symptoms such as loose stools, nasal discharge or a cough during the preceding two weeks but these are either not recognised as significant (because they are so common, and usually fairly unimportant provided they are seen to) or are so slight that trouble is not anticipated. A few parents consult their doctors but treatment or admission to hospital is rarely considered to be necessary. Some of the children die shortly after discharge from hospital and are, therefore, presumed to have been well.

In the majority of cases one of the parents goes unsuspectingly to the infant's cot and finds him dead. The reaction of different individuals varies but few people would be unafraid and it is probable that many panic. There may be attempts to resuscitate and urgent calls are made for the family doctor or the baby is rushed to the nearest hospital. Death is confirmed after a brief examination but the doctor cannot issue a death certificate because the cause of death is unknown and he has to inform the Coroner.

The Coroner has the duty of inquiring into deaths to ensure that they do not have an unnatural or preventable cause. His investigation begins by a visit to the house by a police officer who inspects the place where the child died and takes a preliminary statement. The body of the child is removed to a public mortuary for post-mortem examination. If the Coroner is satisfied that death is due to natural causes he need not hold an inquest and in this case he simply issues the parents with a death certificate. When he decides that an inquest is necessary the parents are given notice to attend the Coroner's Court and beforehand one of them is usually asked to go to the mortuary to identify the body of the child. At the inquest evidence about the death is heard and it is explained to the parents who have the opportunity to ask questions. Following this a disposal certificate is usually given and the parents are then free to arrange for the child's funeral.

Autopsy Results.

Post-mortem examinations show that most of the infants are reasonably developed, well-nourished and display no evidence of neglect nor of overt ill-treatment. Sometimes a little frothy mucus, or vomited milk, is found in the mouth, nostrils and upper respiratory tract but this is not sufficient to cause death. The lungs often contain a small amount of fluid which may be blood-stained. Tiny haemorrhages (*petechiae*) are commonly found over the heart, lungs and thymus gland but they do not occur in all cases and their importance is uncertain. Early changes in the thymus gland and the spleen suggestive of a response to stress are often present.

Attempts to isolate harmful bacteria and viruses from dead infants have not been consistently successful and no single organism has been incriminated. Nevertheless, viruses can be grown from post-mortem samples taken from about half of the children dying from Sudden Infant Death Syndrome. This is twice the rate of virus isolation from control groups of children dying from other causes. Adenoviruses (adeno=glandular) and rhinoviruses (rhino=nasal) have been the predominant types grown but as well as these various enteroviruses (entero=intestinal) have been isolated so that it is possible that several viruses can be responsible for death.

Theories of Cause.

The precise cause of Sudden Infant Death Syndrome is still quite unknown, but there have been several diverse theories advanced to explain it. Most people believe that it is due to a critical combination of factors rather than to a single cause. Many consider that viral infection plays a major rôle in the death of a great number of the infants but exactly how it kills is uncertain. The following is a résumé of the alternative explanations that have been proposed.

Nasal obstruction due to infection, allergy or other causes may lead to asphyxia because some babies are almost completely unable to breath through their mouth. It is certain that their reaction to nasal obstruction is different from that of adults. A cool environment increases the need for oxygen and if respiration is made difficult by a blocked nose a fatal deficiency of oxygen supply may quickly develop. The idea is that this sequence of events occurs in babies with upper respiratory infections during winter nights and that they die from asphyxia of very rapid onset.

Nasal infection may lead to a fatal outcome in a different way. Sudden death has occurred in

animal experiments in which mechanical stimuli have been applied to the nose of young rabbits in the second and third weeks of life. Death was not prevented by ensuring an adequate airway through an artificial passage into the trachea (tracheostomy) but it was prevented if a local anaesthetic was applied to the nostrils. This suggests that it is mediated by the nervous system rather than by nasal obstruction and that arrest of respiration is the result of a nervous reflex.

Another group of theories about the cause of Sudden Infant Death proposes that death is due to heart failure. The mechanism controlling the rate and regularity of heart beats is less stable in children than in adults and processes connected with progress towards maturity (maturational changes) occur during early infancy. It has been postulated that abnormal and ineffective contractions of heart muscle fibres (fibrillation) from which death is very rapid may be precipitated in infancy by stimuli that would be innocuous in older children. Others have suggested that abnormal conductivity is the result of biochemical changes in the ratios of sodium and potassium in the heart muscle which may also precipitate irregular heart action. Recently, tiny haemorrhages have been demonstrated in the region of the heart's conducting tissues and it has been suggested that the disturbance that they cause may account for death by interfering with the heart's action and causing heart failure.

A severe allergic reaction (anaphylactic shock) is another possible cause of Sudden Infant Death Syndrome. The absence of specific post-mortem findings is consistent with the idea and it is known that the anaphylactic reaction is modified by sleep. There is a presumption that the infants are allergic to cow's milk protein, a belief supported by the lower incidence of unexpected death in breast-fed babies and by experimental evidence that milk dropped into the larynx of previously sensitized guinea pigs results in respiratory arrest. On the other hand, small amounts of milk are frequently found in the upper respiratory passages of babies and many bottle-fed infants who do not die have demonstrable antibodies to cow's milk.

A variety of biochemical abnormalities have been proposed as causes of Sudden Infant Death Syndrome. One research worker has claimed that it is due to an incomplete development of the parathyroid glands (P44(1)) causing abnormal levels of calcium. Another has suggested that it is due to magnesium deprivation in infancy. Selenium and Vitamin E deficiencies are yet further theories of cause.

Finally, it has even been suggested that a very small proportion of the infants are killed by mothers suffering from unrecognised depression after childbirth. Evidence of haemorrhages around the spinal cord have been reported from a small post-mortem study of infants who had died unexpectedly. It is not generally believed, however, that infanticide plays a significant part but it may be the cause in a very small proportion of cases.

Social Consequences.

The initial reaction of parents, reasonably enough, is one of shock and grief. To this is added anxiety and possibly fear because of the legal processes in the ensuing few days. Lack of a clear explanation for the death and the absence of definitive post-mortem findings create further problems. It is easily understandable that in these circumstances most parents are confused and the lack of "official" reasons for their baby's death leads them to search for their own explanations.

There is a great unmet need for some informed person to whom parents may talk in an unhurried way in the succeeding weeks. Many may turn to their family practitioners, but some are unable or unwilling to do this especially if they have consulted him about the baby immediately before death or if they were not able to contact him quickly at the time of crisis. Pathologists have sometimes undertaken this rôle as have Health Visitors and Ministers of Religion. There is also a voluntary society (Foundation for the Study of Infant Deaths (Welfare Office), 23 St. Peter's Square, London, W6 9NW), which can help by providing leaflets for parents.

Apart from the shock and possible feelings of guilt and confusion parents may easily lose confidence in themselves as parents. Unsympathetic reactions of neighbours will tend to detract further from their pride in parenthood. They are bound to ask themselves whether the same tragedy will happen with subsequent children and future infant rearing is certain to be shrouded with anxiety. The serious effects of this on the parents and their children can be reduced by the patient explanation by experts and the sympathetic understanding of friends.

Confidence in the medical services has also to be restored because these are important to the welfare of the parents and their future children. It is generally true that parents are not to blame and should not blame themselves. Medical and nursing personnel are not to blame either and are often perplexed and upset by an event that they are unable to explain. The problem is that the cause of Sudden Infant Death Syndrome is not known and it is difficult for people in modern developed nations to accept such lack of knowledge.

Prevention.

There is a need for continuing research not only for humanitarian reasons but also for the economic reason that the loss of life in years surpasses that of many of the common fatal diseases of adults. Much work has already been done on the epidemiological and pathological aspects of Sudden Infant Death and advances in our understanding of the subject are now likely to be achieved by a study of the interrelationship of minor illness and social conditions. In addition, observations are being made on infants who have been resuscitated from "near death" and these may be a fruitful source of information in the future. In the meantime the best that can be done to prevent these deaths is to encourage breast-feeding of infants and to ensure that, so far as possible, mothers are able to recognise early signs of illness and to take appropriate action. Since it is possible to identify babies at greatest risk, on the basis of information which is now available, the assistance of Health Visitors and other community medical services should be concentrated upon them.

Secondary psychiatric problems can be reduced by making the necessary legal enquiries as humane as possible. Much depends on the tact of the police officer who makes the initial visit and fortunately they are usually experienced people who are used to dealing with this kind of problem. There is a case for the employment of plain clothes women officers for these tasks so that local curiosity is not aroused. In most cases inquests are not necessary and are not held but where the question of an unnatural or preventable death has been raised the matter must, in the parents' interests, be dealt with clearly and definitely. Wherever possible they should be given a cause of death which they are able to understand even though the diagnosis may be based on reasonable supposition rather than pathological proof. Finally, a counselling service should be organised to which parents may be referred when consultation with their family doctor is not appropriate. In these ways a good deal of mental anguish can be prevented.

ORAL CONTRACEPTIVES AND DEPRESSION.

The "pill" is now widely accepted by many (and in some communities most) women as a convenient, effective and relatively safe method of birth control. An estimated fifteen million

women throughout the world use this form of contraception which is usually, but not always, prescribed under medical supervision.

Its efficacy is taken for granted; there are certain untoward results ("side-effects") which may, or may not, be reported to the prescribing doctor. Most of these are minor and of no consequence—transient nausea, digestive upsets and usually some weight gain. The more serious side-effect of an increased tendency to thrombosis has had a good deal of publicity in the National Press and been the subject of a careful investigation by the Committee on Safety of Medicines. It was found that the thrombotic tendency (a virtually normal characteristic or side-effect of pregnancy anyway) was related to the size of the oestrogen component of the pill and a recommendation was made that only those pills containing not more than 50 microgrammes of that component should be on the market—the so called "mini-pill."

Since then, the incidence of thrombosis in women taking oral contraceptives has fallen to an acceptable level—*i.e.*, the risk is now no greater than that in normal pregnancy.

Although the increased predisposition to thrombosis drew all the publicity (because it was sometimes a cause of tragically sudden death), the contraceptive pill does have other effects which because they lead to no overt signs are not widely known and are seldom reported, even in the medical journals.

One of these is the effect on the body's capacity for dealing with sugar. The two drugs commonly used in the "pill" act in the same way as naturally-produced hormones do during a normal pregnancy, by inhibiting ovulation. Changes in body chemistry also take place—as they do in pregnancy—and these changes concern water balance and the metabolism of foodstuffs (fat, carbohydrate and protein). Thus, during the months and years of "pill"-taking, water-retention occurs (leading sometimes to oedema) and the capacity to deal with glucose becomes impaired—as it is in diabetes. These changes are readily demonstrated by special techniques such as the *glucose tolerance test* which measures the rate at which a test dose of sugar is removed from the circulating blood for energy storage in the liver and other tissues. The significance of this impairment is not known but at least doctors are aware of it as a "pill" side-effect and would be on their guard when considering the question of prescribing for a woman with, for example, a family history of diabetes.

But one of the more intriguing side-effects of "pill"-use recently investigated, but little publicised, is the apparently higher incidence of *depression* among women taking either the standard *or* the mini-dose preparations. When this occurs it can be either a minor irritation or of more serious import leading to much misery, unhappiness, marital disharmony and even suicidal thoughts. Stopping the pill relieves the depression; indeed it is not an uncommon reason for women giving up the oral contraceptive either through their doctor's advice or simply on their own initiative.

Body Chemistry and Depressive Illness.

Biochemical causes for psychiatric conditions are constantly being sought but seldom found. Mental changes occur in certain vitamin deficiency diseases and respond to correction of the dietary deficit. There is no doubt that the brain is sensitive to subtle changes in biochemical balance and it is well known that the mind is readily influenced by a variety of chemical compounds or drugs. But depressive illness, so common in our society, does not appear to be associated with any detectable change in the body's chemical make-up and its origins and causes remain obscure. In depression occurring in women on oral contraceptives, however, changes *have* been detected and these indeed might give a clue to some underlying biochemical disturbance in other types of depressive illness.

Careful biochemical investigations in "pill-depression" have led to a rational, effective treatment that can be administered while the contraceptive is continued. That the remedy is in fact the correction of a temporary depletion of one of the B-group vitamins—B6 or pyridoxine—is intriguing in view of what has been written above. In fact, the remedy was found *before* the biochemistry was unravelled—by a team working in a specialised metabolic unit at St. Mary's Hospital, London.

Although it is estimated that only about one in five women taking the contraceptive pill in fact get depressed, their symptoms are often severe enough for them to seek medical advice and treatment. The complaints are of tiredness, lethargy, dissatisfaction, pessimism, tearfulness and tension; sleeping and appetite are, however, nearly always unaffected—in contrast to other types of depressive illness. The classification of depression is still a matter of dispute among psychiatrists and need not concern us here. "Pill depression" is real enough and deserves a classification of its own. It is unique among the depressive syndromes in that we have good evidence that it is *biochemically determined*. In other words, it results from specific changes in body chemistry which can be demonstrated by analytical techniques in body fluids such as blood and urine and which can be normalised by administering comparatively small doses of vitamin B6.

Medical research workers are constantly seeking organic, treatable causes for psychiatric disorders and inevitably, as techniques for untangling complex biochemical systems are developed, more of these disorders are "screened" by analytical methods in the hope of finding some clue to a possibly correctable derangement. Depressive illness itself has had a lot of attention since the unexpected discovery that *monoamine oxidase inhibitors* have a specific effect on mood. It has long been thought that certain nitrogenous substances (amines) found in brain tissue are less concentrated in depressed patients than in normal people, and there is evidence that this is a result of defective synthesis from precursor substances which are derived from dietary protein.

One such amine is *serotonin* (5-hydroxytryptamine) which is in turn derived from an important amino acid, *tryptophan*. The amino acids themselves (F27(1)) are the "stuff" of protein, simple nitrogenous compounds which result from the hydrolysis or digestion of animal and plant foods. Tryptophan is also the starting-point for another series of metabolic intermediates which result in the formation of important enzymes required for the metabolism of carbohydrate and protein.

Impaired Tryptophan Metabolism.

It so happens that the way the body "handles" tryptophan can be readily monitored by giving an extra amount of the substance by mouth and measuring the output of the various derived substances in the blood or urine. In the normal situation the body can cope with such a "loading dose" and there is little or no increase in the amount of derived substances (metabolites) found in the urine. In vitamin B6 deficiency, during normal pregnancy *and* in women taking oral contraceptives these substances are not handled properly and are consequently found in greatly increased amounts.

What then has an impaired tryptophan metabolism (as demonstrated by the loading test) to do with depression? We have seen that tryptophan is the starting point of the synthesis of *serotonin* and other amines and it is believed that serotonin is lacking, or relatively scarce, in the cerebrospinal fluid of *some* depressed patients. It will also be remembered that tryptophan not only provides a starting point for serotonin synthesis but is involved in other synthetic pathways as well. What the tryptophan loading test appears to indicate is a preference for those *other* pathways, to the exclusion, partly or wholly, of that which leads to serotonin. As far as the situation in pregnancy and in women taking the pill is concerned, the sex-hormone *oestrogen* has been implicated as a factor in the change from one tryptophan pathway to another.

Thus we have the situation that even the very small dose of oestrogen used in the "mini-pill" may upset the normal "body-handling" or metabolism of tryptophan. Indeed it has been shown that 80 per cent of women who take the oral contraceptive regularly have such a biochemical upset. And because of the intimate

dependence of many of the steps in the metabolic pathways leading from tryptophan on *enzymes* which are themselves derived from the water-soluble vitamin B6, a relative deficiency of the vitamin is induced. This has been clearly shown to occur in pregnancy and in "pill" takers.

The diversion of tryptophan along a preferential pathway by the action of oestrogen (whether endogenous or exogenous—*i.e.*, whether occurring naturally, as in pregnancy, or given by tablet or injection) leads to relatively less of the substance being available for serotonin synthesis and hence less of that essential amine in the cerebral circulation. This is a simplified view; in fact there are two other possible mechanisms underlying a relative serotonin deficiency and the interested reader is referred to the many published papers on the subject. It was a study of those mechanisms that led to the first use of vitamin B6 in "pill" depression when it was realised that the relative B6 deficiency induced by abnormal tryptophan metabolism could *also* effect serotonin production. This is because the vitamin is essential in the last stage of serotonin synthesis and, whatever the minutiae of the mechanism involved, giving vitamin B6 to pill-depressed women relieves their symptoms.

To simplify the story: oestrogen in the "pill" effects tryptophan metabolism in a way that diverts it from its role as a serotonin producer; vitamin B6 is "used up" in a number of biochemical changes including the synthesis of serotonin from its immediate precurser; serotonin synthesis is therefore at a double disadvantage.

When the suggestion was first made and tablets of vitamin B6 hopefully administered to patients the effect on depression was not consistent. Some patients improved but some did not. Because of the possible implications for therapeutic advance in the treatment of depressive illness generally, not just for the relatively small number of "pill" sufferers, the whole question has fairly recently (1973) been thoroughly investigated in a controlled clinical trial which was carried out at St. Mary's Hospital, London. *See Lancet* (1973): (i) 897–904.

The biochemical study and the clinical trial associated with it have clearly shown that not all the depressed patients had evidence of vitamin B6 deficiency; but those that had, responded to treatment with the vitamin, whereas those that had no such evidence *did not*. We now have a situation in which a fairly clear-cut pathological condition with easily identified symptoms has been shown in all probability to have a clearly definable biochemical cause. The steps in its genesis are readily identifiable and its treatment absurdly simple. In itself this is not one of medicine's great breakthroughs but may well be a significant pointer to the way in which other pathological mental states may eventually be found to have biochemical causes remediable by equally simple and safe substances. Vitamin B6 is without toxic effects even in large doses; those used in the treatment of the condition under discussion are only of the order of 40 mg a day—about 10 to 20 times the amount found in a normal day's diet.

Clinical Trials.

It may interest the reader to know how the study and trial was carried out. All trials of new medicinal substances (or retrial of old ones!) whether they be drugs or food factors such as the vitamins, are essentially comparisons of the new treatment with either the existing standard regime or with no treatment at all. In the depression trial it had to be the latter as there was no standard treatment.

But if "something" is compared with "nothing" then improvement in a proportion of those patients having something (even if the "something" has in fact no measurable effect in itself) will occur simply because the doctor himself unconsciously plays a potent therapeutic rôle when he prescribes that "something." This of course is particularly true in psychoneurotic illness like depression. If therefore the "no treatment" group is to be the yardstick against which progress of the "treatment" group is measured, then those patients must have "something" too. The plan is therefore to see and "treat" all patients alike but to ensure that a proportion (usually half) have the drug under investigation and the rest have a tablet, capsule or mixture that looks exactly the same but is made up of known ineffective substances like milk-sugar (lactose). Both groups will have the same medical and nursing attention, the only difference will be the "medicine." It is essential in this situation that neither the doctors nor nursing staff should know which patient is having what—nor indeed should the patient know. Both are "blind" to the true situation. Preconception, prejudgment and bias are eliminated. This is the controlled "double-blind" trial. The two groups are referred to as "active" and "control"; the comparison is between the *drug*—which the active group are given and the *placebo*—which the control group have. (The word placebo is Latin and means "I please".) The method ensures that those who are to have no treatment in fact get something. Allocation of patients to one group or another is by chance or "random selection." Clearly, ethical considerations must come into certain drug trials, if not all, but discussion of these is beyond the scope of this article.

From the potential group of women suitable for inclusion in the trial were excluded all those with an obvious "outside" cause for their depression—marital disharmony, money troubles and so on—and those with a previous history of mental disturbance before even the contraceptive had been started. In the event nearly 40 women with depression severe enough to warrant treatment entered the trial over a period of nearly three years. Each patient required several hours of attention over a period of about four months, during which she made five or six visits to hospital, each visit requiring that she should stay for two or three hours.

The trials have shown that half the women who develop depression while on oral contraceptives have an induced vitamin B6 deficiency as an indirect result of the medication. Those women benefit from administration of the vitamin in doses rather greater than are being consumed in the diet, and the depressive state responds to that treatment. If there is no demonstrable deficiency then there is no effect from vitamin treatment. The story is not a simple one and clearly there are other factors at work beside the tryptophan-serotonin-vitamin B6 hypothesis which is so attractive as a biochemical explanation of the condition. The problem is not large although with the steady increase in oral contraceptive consumption the number of patients requiring treatment because of depression will also increase if the present *proportion* of depressed individuals remains the same.

There is as yet no simple clinic test for vitamin B6 deficiency but pyridoxine can always be prescribed on a "trial and error" basis. On the evidence so far presented *half* the patients will respond. It has been suggested that women who are given the contraceptive should also have vitamin B6 prescribed at the same time. In some European countries it is combined with the "pill" itself.

Depression is one of the commonest ills of our time. The possibility that it might have a biochemical basis has exercised the minds of research workers everywhere. The discovery that in one type of depression there is such a biochemical foundation is significant and exciting and provides a stimulus to renewed activity in the broader areas of mental illness. Treatment of mental disease in general and depression in particular is still largely empirical and the drugs used are potent and potentially harmful. They are prescribed by the million each year; we may simply be using mallets to crack the shells of only lightly boiled eggs.

A BALANCED DIET.

The phrase "a balanced diet" is one of the clichés of nutritional writing. It is often assumed to be self-explanatory, but it is in fact a very difficult thing to define. The Manual of Nutrition of the Ministry of Agriculture defines a balanced diet as one which contains all the nutrients in the required proportions. The concept is unexceptionable: its practical application however

presents difficulties. Chief of these is that one does not strictly know how much is required of any nutrient, much less of them all. Official recommended intakes serve as a guide, but these are provided for only a few of the nutrients: protein and some vitamins and some minerals. The major sources of energy—fat and carbohydrate—are usually omitted from official tables. Again the Ministry argues that adequacy of the diet can be safeguarded by the inclusion of as wide a variety of foods as possible, and meals are said to be well balanced when they provide adequate amounts of proteins, minerals, vitamins, and energy.

The concept of a balanced diet as one providing all known nutrients in the required amounts has undoubtedly been useful for work with animals in the experimental laboratory, and to a large extent also in intensive farming situations. It is common practice to prepare so-called purified or semi-purified diets, or to formulate standardised rations, which are capable of maintaining growth and reproduction and a high level performance, for example in egg production. Here the animals consume an unvaried diet, each gram of which contains the desired proportion of nutrients. Problems can arise because the balance for fastest growth may not be the same as that leading to longest life, or low incidence of disease, or leanest carcase, or other measure. However, in human situations the concept is much less useful. It has of course value to the professional nutritionist, even though the question of an optimum balance is so much harder to resolve for man than for animals. Usually the question is ducked by saying things like "optimum" is "adequate," and "adequate" is "sufficient." But as a basis for practical nutrition education its effectiveness is doubtful. Sometimes those concerned with nutrition education seem to argue that people should have a quantitative knowledge of nutrient requirements on the one hand, and a complimentary knowledge of food composition on the other hand; these two types of knowledge, coupled with a knowledge of food prices, would then enable sensible decisions to be reached about inexpensive balanced diets. But people do not, nor is it likely that many ever would, make decisions on such a basis about the foods they eat. Nor is it desirable that they should be persuaded to try to, because the few who might be tempted would in all likelihood develop such a neurotic anxiety about their food that they would suffer in this way much more than they might possibly have done from any imbalance—imagined or otherwise—in their diets. Popular nutrition education should relate to foods, since these are what people actually eat. Emphasis on nutrients is misguided because in practice it has led to distortions and faddism.

Some Misconceptions.

One of the distortions is the undue emphasis placed so frequently on protein. Most foods contain protein, and in fact it is difficult to devise a diet acceptable to the ordinary Briton that does not contain substantially more than the minimum requirement for health. As long ago as 1917 Professor Bayliss coined a phrase which, in the context of the sort of diets eaten in Britain, is equally valid today: "take care of the calories and the protein will take care of itself."

Another distortion is the emphasis often given to vitamins, and their alleged deficiency. This has given rise to the not uncommon view, for which there is little objective basis, that it is necessary to supplement a normal diet with expensive pharmaceutical preparations. This is, at the least, a wasteful expense; at the most, a danger to health, since too much of some vitamins is definitely harmful. Of course, one should not adopt a too extreme position: supplements can be useful and those provided by the Department of Health's welfare schemes for young children and expectant and nursing mothers are a sensible precaution. Rickets does occur in Britain today, especially in some immigrant communities; so occasionally does scurvy. These diseases are due to deficiencies of vitamin D and of vitamin C respectively, and it is sensible to ensure that sources of these vitamins are included in the diet.

But, in fact, the incidence of disease due to inadequate dietary intake of vitamins—or of most minerals—is exceedingly small. Failure to recognise this is perhaps one of the reasons for the popularity of so-called health foods. "So-called" because in fact there is no worthwhile evidence that foods sold in "health food" stores are any more "healthy" than those sold elsewhere. Indeed by many objective criteria, such as degree of bacterial contamination, frequently they are a good deal less "healthy." Much nonsense is talked about the alleged nutritional superiority of "health foods" or "natural foods." What is "natural" anyway? A dictionary definition is "a primitive undomesticated condition . . . not interfered with by man . . ."; clearly, on this basis, nothing produced by agriculture—whether ancient or modern—can be called "natural." So what?

It is important that people are disabused of the notion that foods bought at "health food" shops are any more nutritious than their usually less expensive conventional counterparts. It is equally important that people do not suppose that they are any more safe. Neither supposition is generally true. No doubt differences in composition between samples of similar food can sometimes be demonstrated, but the relevant question is whether such differences are significant from the nutritional or toxicological point of view: except in some bizarre circumstances they are not. Circumstances in which differences could be important are when extreme faddist principles seriously restrict the variety of foods consumed: indeed it is in such circumstances that nutritional deficiencies are not uncommonly found. For example strict vegans who abjure all foods from animal sources, run the risk of pernicious anaemia because of deficiency of vitamin B12, a vitamin of uniquely animal origin.

There are two other reasons why some people patronise "health food" stores or seek "natural" or relatively unprocessed foods. One is that they find some of the produce more palatable. Questions of palatability involve subjective judgment, nonetheless valid for that to the individual concerned, who if prepared to pay extra for the satisfaction of his taste buds is of course entirely entitled to do so. But he should not confuse satisfaction of his palate with satisfaction of his nutritional needs. The style of our society has created an increasing demand for convenience foods of all sorts, and while the gourmet may deplore the trend, there is no nutritional reason for faulting it: nutritious meals are not necessarily dull, and neither are foods that could hardly be called a gourmet's delight for that reason any the less nutritious. The two aspects are distinct.

A fourth reason that some give for patronising "health foods" or "natural foods" is that by doing so they believe they are demonstrating their concern for the environment and ecological balance in nature which they believe are threatened by the values of contemporary western society. Certainly in the United States the demand for "natural foods" is sky rocketing, partly perhaps for this reason, and many producers are finding it economic to meet this demand in spite of higher production costs and lower yields. No doubt we shall see much more of this in Britain too. Many would regard those who hold such views as misguided; some may think of them as prophets of a future saner age; but whether fools or seers it is well to recognise that arguments about nutrition or toxicology are irrelevant to their purpose.

"Health food" extremists are unlikely to be deterred by the fact that modern urban society in Britain would be impossible were their particular views on food supplies to be implemented universally; or they might apply to themselves Kant's Categorical Imperative which may be rendered: what would be wrong for all, is wrong for one. Freedom of action in this sphere is a privilege denied to the great majority.

Energy Input and Energy Output.

Extremism has no place in any pattern of sensible eating. Undue emphasis on nutrients may have contributed towards extremist views, and distracted attention from the major problems of nutrition in Britain today. What are these problems? Dental caries is a national scourge, with an accepted dietary basis. Heart and blood

vessel disease is the main cause of death with an accepted relationship to diet, even if the precise nature of this relationship is disputed by the experts. But perhaps the major manifestation of malnutrition in Britain today is obesity. All manner of diseases are more serious in the obese individual. Too many people eat too much food (obtain too much energy) in relation to their energy expenditure. The most important aspect of " balance " is the balance between energy input and energy output. It is perfectly apparent that people must obtain adequate nutrition from an immense variety of diets. Were this not so, nutritional deficiencies would not be the relatively rare occurrence that they are. Far more important than the quality of the diet, in Britain today, is the quantity of the diet. Gluttony may or may not be sinful: it is certainly foolishness. The old adage: " a little of what you fancy does you good," is in fact sound nutritional teaching, provided that the emphasis is placed on the words " a little." And it helps if " what you fancy " is pretty varied. A good rule would be: " experience foods widely: indulge appetite temperately." Or " variety in moderation," provided it is understood that what should be moderated is not the variety of foods but their amount. A distinguished nutritionist puts it thus: " eat a little of everything and not too much of any one thing." An old piece of doggerel concludes with the line: " un oeuf is as good as a feast "; the point is well taken. Indeed many of the old-fashioned virtues could with advantage be resurrected with a modern nutritional justification: conclude each meal feeling that you could eat more; never accept a second helping, unless you would normally accept a third; not, perhaps, leave a little of each course on the plate, but certainly do not take more than you can, in all conscience, consume. But destroy the notion that it is somehow immoral not to consume all that is prepared—better to believe that it is immoral to prepare more than should be consumed.

Of course such moral injunctions are not appropriate to every individual, but this article is concerned with major priorities for the many. Good intentions too are insufficient for a large number of overweight people, who need the motivation that can be provided, for example, by participation within a group in programmes of controlled eating behaviour. Some of the dietary " rules " of such groups may have little strictly nutritional justification, but it may be valid as expedient means of self discipline, and it is in that light that they should be judged.

But perhaps such advice is not sufficient. If energy intakes are to be reduced, is this to be achieved by a proportionately similar decrease in the consumption of all foods? If nutrient intakes are to be maintained, should not sources of " empty calories " (*i.e.* those foods such as sugar and alcoholic drinks which supply energy but no appreciable amounts of nutrients that serve any other function) be reduced proportionately more than other foods? Nutritional considerations would indicate that they should be so reduced: to what extent it is not so easy to say. Today sugar provides on average 17% of the total calories in the diet (excluding alcohol); the variation about this mean must be substantial, and many individuals must be obtaining a nutritionally quite unacceptable proportion of their calories in an empty form. During the second world war sugar provided only 11% of the dietary calories, and because of rationing it is unlikely that there was much variation about the average figure. If average sugar consumption today fell to this level there is no reason to suppose that any nutritional harm would result, and much benefit might well accrue; such a level, tolerated by this country in the fairly recent past, may therefore be regarded as a goal.

Beneficial Dietary Changes.

There is some support for the view that such a reduction in sugar consumption might be beneficial from the point of view of cardio-vascular disease. There is more support—though by no means unanimity amongst the experts—for the view that reduction in total fat intake would be beneficial in this regard; and some believe that the evidence for the benefit of an increased proportion of poly-unsaturated fatty acids in the fat component of the diet is sufficient to merit action. Since there is no reason to suppose that dietary changes of this nature would result in any harm to the individuals adopting them, and since they might in fact lead to a longer and more healthy life, they would seem to be sensible measures to adopt.

In order to maintain a sufficient supply of vitamins and minerals the consumption of green and yellow vegetables and of fruit should be maintained, if not increased: some forms of citrus fruit (as a source of vitamin C) at breakfast is a sound—if only expedient—nutritional rule. However, these foods provide few calories and if consumption of sugar and of fat is to be decreased in their own right, so to say, it is possible that the consequent reduction in energy intake would be greater than desired. This would imply the need for some increase in consumption of predominantly starchy foods, notably of bread. Recent awareness of the possible importance for many diseases of dietary fibre, especially that in wheat, suggests that more emphasis might have to be given than hitherto to wholemeal bread. Research in the next few years should throw light on this potentially important topic.

Changes in the dietary habit of the nature outlined above have fundamental implications, and would be excessively difficult to promote, since with only minor exceptions they run counter to all recent experience. It is well recognised that trends in patterns of food consumption associated with increasing affluence are characterised amongst other things by an increase in dietary energy availability relative to requirements, an increase in the proportion of energy derived from fat at the expense of that from carbohydrate, and a displacement of starch by sugar. These trends are seen whether one compares nations (or groups within nations) of different levels of affluence at the same point in time, or examines changes within a country over a period of time. Those groups low on the socio-economic scale have a relatively low consumption of fat and of sugar and a high consumption of starch, but there is no reason to suppose that those high on the socio-economic scale (such as, relatively speaking, most people in Britain) have not passed beyond the " optimum balance " in these regards.

Unfortunately in the present state of knowledge it is not possible to assert with confidence what the optimum balance should be. But it is desirable that a judgment should be made on the basis of such evidence as is available, about the sort of balance that would be sensible. Such a judgment might be that sensible eating for many people in Britain today implies an increase in consumption of fruits and vegetables and of bread (especially wholemeal bread); little change in consumption of milk, cheese and meat (but avoidance of their fat), and perhaps increased consumption of fish; and reduced consumption of fats and oils (except those rich in poly-unsaturated fatty acids which might even be increased), of sugar and sugar-containing foods (such as cakes, biscuits and pre-eminently sweets), and of alcoholic drinks.

But above all, sensible eating implies moderate eating: restraint in the quantity, though not in the variety, of foods consumed.

This article has been adapted from Bulletin No. 9 (1973) of the British Nutrition Foundation with their kind permission.

PART IV. INDEX AND GLOSSARY

Abortion. The termination of pregnancy, from whatever cause, before the child is capable of independent existence, 56.

Abortus fever. An infectious disease known as undulant fever, 15 (1).

Abrasion. Any injury which rubs off the surface skin.

Acidity. *See under* Peptic ulcer, 36 (1).

Acne, 53 (2).

Acromegaly. A state of excessive growth of the body caused by overaction of the pituitary gland in the base of the brain, 43 (2).

Actinomycosis, 15 (2).

Acute chorea or St. Vitus' dance, 49 (1).

Acute nephritis, 45 (1).

Addiction to drugs. *See* Drug abuse, 22.

Addison's disease, 43 (2).

Adenoids, 32 (1).

Adrenal cortex, 43 (2).

Adrenal medulla, 43 (2).

Adrenocorticotrophic hormone (ACTH), 43 (2).

Air we breathe, 4 (1).

Agranulocytosis, 26 (1).

Alcoholics Anonymous, 6 (2).

Allergy. Abnormal sensitivity to any substance which does not affect normal people.

Alopecia, 52 (2).

Amenorrhœa, 56 (2).

Amnesia, 47 (1).

Amœbæ, 8 (1).

Amœbic dysentery, 17 (2).

Amphetamine, 23 (2).

Amyotrophic lateral sclerosis, 48 (2).

Anæmias, 24–25.

Anæsthetic. Any drug used by surgeons to remove pain during an operation.

Anencephaly, 48 (2).

Aneurism, 30 (2).

Angina pectoris, 28 (2).

Ankylosis. Partial or complete fixation of a joint as after some types of arthritis. In other cases deliberately produced by surgery.

Ankylostomiasis, 16 (2).

Anorexia. Loss of appetite.

Anterior pituitary, 43.

Anthrax, 15 (1), 9 (1), 4 (2).

Antibiotics are drugs which act directly against the organism causing the illness by interfering with its growth or some other aspect of its living mechanisms. Of all drugs which are used against bacteria, antibiotics do least harm to the patient's own tissues; some do have unwanted side-effect, but many have none at all. *See* 4, 9, 22.

Antihistamine drugs, 4 (2), 5 (1).

Antiseptics, 8 (2).

Anxiety neurosis, 51 (2).

Aortic diseases, 30 (2).

Aphasia, 47 (1).

Aplastic anæmia, 25 (1).

Appendicitis, 37 (1).

Arteriography, 48 (1).

Arthritis, 54 (2).

Artificial respiration (kiss of life), 21 (1).

Ascites, 39 (1).

Asphyxia, 20 (2).

Aspirin and "upset stomach", 5 (1), 23 (1), 36 (2); *see also* Headache.

Asthma, 32 (1).

Atheroma or Atherosclerosis, 30 (1)

Athlete's foot, 8 (1), 15 (2).

Backache. A symptom which may be caused by many different diseases—sometimes disease of the vertebræ themselves, sometimes strain of the ligaments, and sometimes inflammation or spasm of the surrounding muscles. "Lumbago" is usually due to inflammation of the muscles in the small of the back. Backache from purely local causes may be treated temporarily by applying heat in the form of a kaolin poultice or a rubber hot-water bottle and taking two aspirin tablets a day. On the other hand, many cases of backache are due to disease elsewhere. The most important thing is to find out the cause, and therefore a doctor should be consulted.

Bacteria, 7 (1). **Bacterial diseases,** 12–15.

Bacteriophage, 7 (2).

Baldness, 52 (2).

Barber's rash, 53 (2).

Barbiturates, 23 (2).

Bell's palsy, 50 (2).

Benzedrine. The proprietary name of a drug known as amphetamine. *See* 23 (2).

Beri-beri, 42 (2).

Berry aneurysm, 49 (2).

Bilharzia, 18 (2), 16 (1).

Birth control, 56. *See also* Oral Contraceptives.

Blackwater fever, 17 (2).

Bladder. *See under* Urinary diseases, 44 (2).

Bleeding diseases, 26 (1).

Blepharitis, 55 (1).

Blood, function of the, 24.

Blood, diseases of the, 24.

Blood Groups. Human blood plasma contains factors which clump, or agglutinate, the red cells of some other people's blood. The main blood groups are called A, B, AB, and O. The plasma of group A blood contains an anti-B factor and *vice versa*, so that people of groups A and B cannot accept each other's blood. Group AB contains neither anti-A not anti-B factor and people with this group can therefore receive transfusions from both but can give to neither. Group O contains both anti-A and anti-B, and can therefore receive blood only from group O but can donate blood to all groups. It is important that transfused cells should not be agglutinated by the factors in the recipient's plasma. Apart from the so-called ABO system, there are several other blood groupings, one of which is mentioned under **Rhesus Factor.**

Blood poisoning (septicæmia), 14 (2).

Blood-pressure, 29.

Blood-vessels, diseases of the, 30.

Blue babies, 5 (2).

Botulism, 14 (1).

Brain. *See under* Nervous system, 46, Physical injuries, 19.

Brain tumour, 50 (1).

Breasts, 55 (2).

Bronchial asthma, 32 (1)

Bronchiectasis, 32 (1).

Bronchitis, 31(2).

Bruises and abrasions, 19 (2).

Bürger's disease, 31 (1).

Burns and scalds, 21 (2).

Cachexia. Extreme wasting due to disease.

Cæsarean operation. When the abdomen has to be opened to remove the child, named after Julius Cæsar, who is said to have been born in this way.

Caisson disease, 31 (1).

Cancer of the breast, 55 (2).
Cancer of the cervix, 56 (1).
Cancer of the colon, 37 (2).
Cancer of the lung, 33 (2), 34 (1).
Cancer of the œsophagus, 36 (1).
Cancer of the rectum, 37 (2).
Cancer of the stomach, 37 (1).
Cancer test (cervical smear), 56 (1).
Carbohydrates. The scientific name for sugars, starches, and cellulose, 34 (2), 40.
Carbon monoxide poisoning, 21 (1).
Carbuncle. A large boil.
Cardiac neurosis, 27 (1).
Cataract, 55 (1).
Cerebral abscess, 49 (2).
Cerebral embolism, 49 (1).
Cerebral haemorrhage or apoplexy, 49 (1).
Cerebral palsy, 48 (2).
Cerebrovascular diseases, *see* **Stroke illness.**
Chadwick, Sir Edwin (1800–90). English social reformer, 6.
Chancroid, 16 (1).
Change of life, 44 (1).
Chickenpox, 10 (1).
Chilblains, 53 (1).
Child abuse, 63
Chill. This is not a proper medical word, but refers to the symptoms that occur when one first becomes infected with any germs which cause fever. When such germs enter the body, all the defending processes are mobilised and speeded up. The white cells in the blood increase in number, and the amount of energy used is greater than normal, causing the temperature to rise. This rise in temperature increases the ability of the body to fight back, and, in order to retain heat within the body, the blood-vessels in the skin contract so that less heat is lost by radiation. This makes the skin cold and pale. What is ordinarily called a chill is merely an infection by the germs causing cold and influenza. But a chill may be the preliminary to almost any infectious disease, such as measles, mumps, scarlet fever, pneumonia, and so on. The best treatment when the temperature is raised is to go to bed with as much warmth as possible. Hot drinks and hot-water bottles are helpful. *See* **Colds,** 10 (2), 66–7.

Psychosomatic diseases. Psychosomatic diseases are those physical ailments due to emotional causes. They include such complaints as high blood-pressure, gastric ulcer, certain skin diseases, and certain glandular diseases (*e.g.*, exophthalmic goitre). Most physicians nowadays believe that all diseases may show a greater or less degree of emotional causation; that physical and mental factors are both present in all illness. Even in psychosomatic illnesses, heredity and other factors play a large part. Briefly, the main cause of these diseases is worry. The importance of this lies in the fact that they cannot be cured without dealing with the fundamental cause. *See also* New Views on Medicine, 3 (2).

Rhesus Factor. Apart from the ABO blood group system (*see* Blood Groups) there is another blood group system (designated the Rh-system or Rhesus system). Everybody is either Rh-positive or Rh-negative. Three positive factors (denoted C, D, E) and three negative factors (denoted c, d, e) are involved. This system of blood factors is inherited separately from the ABO group, so that one may be A Rh+ or A Rh−, etc. Both the positive and the negative factors are antigenic,

i.e., if introduced into other blood they will stimulate the production of substances which act in some way against the cells introduced. We inherit some factors from each parent and it may occur that a Rh+ baby is born of a Rh− mother. In this case some of the baby's blood may, and often does, obtain access to the mother's circulation and stimulate her to form substances harmful to the baby's red corpuscles. If these leak back to the baby through the placenta some of the baby's red corpuscles may be adversely affected. This does not usually occur with the first baby, but may become increasingly serious with following pregnancies.

Rods and Cones are cells in the retina of the eye which convert light into nervous impulses which can be interpreted by the brain. In man the cones are associated with colour vision and used during daylight. The rods are concerned with twilight vision and do not give rise to the sensation of colour. It is probable that there are three types of cones responding to red, green, and violet, other colours being a combination of these three. Rods contain a pigment, visual purple, which is sensitive to light. Vitamin A is necessary for the production of this substance. The changes produced by light on the visual purple initiate a nerve impulse but the exact mechanism is unknown.

AN INTRODUCTION TO PSYCHOLOGY

This section is concerned with the science and study of the human mind, a territory rich in mystery, a glimpse of which we catch through the enigma of memory, and in the misty drama of our dreams. It represents a unique guide to one of the most exciting experimental sciences of today.

TABLE OF CONTENTS

I. Introduction—discusses the role of the psychologist and his principal fields of study—the brain and human behaviour. 3–7

II. Perception—includes the study of the way information is gathered by the brain and how it is interpreted. 7–16

III. Learning and Memory—deals with the way the information is stored once it has been gathered, and how it is retrieved when wanted. 16–23

IV. Motivation—studies the vital question of why a human or animal interacts with its environment and does one thing rather than another. 23–27

V. Personality and Thinking—tackles the abstruse problems concerned with consciousness, self-awareness, intelligence, thought and language. 27–30

VI. Special Topic—Hypnosis. 31–34

AN INTRODUCTION TO PSYCHOLOGY

The purpose of this section is to provide a general introduction to the young but expanding science of psychology. The topic itself is of course enormously broad and can only be summarised at best. However, it is hoped it will serve to give some idea of the fascinating material that psychologists study and also of their occasionally remarkable, and always interesting findings. The section also aims to dispel some of the illusions that have surrounded the subject and to define its boundaries to the extent that the reader will not only begin to understand what psychology is, but also what it isn't!

I. INTRODUCTION.

What is a Psychologist?

The popular image of a psychologist is a fairly well-defined one—he is a man who treats mental illnesses in the way that a doctor treats physical ones. His principal equipment, apart from a well-furnished "consulting room," is a leather couch for patients to lie on, a well-stocked library, and a cabinet of mysterious drugs of one kind or another to send them off to sleep. He is particularly interested in the dreams of his clients and may use some form of hypnosis to study their "repressed" thoughts and secret emotions. He is probably very wealthy, because of the enormous fees he charges, and may speak with a central European accent.

Silly though the above description may sound, it is nevertheless unfortunately true that it corresponds pretty closely to the kind of picture that most people have of a psychologist and of the kind of work he does. Remote though this description is from the truth—at least as far as the vast majority of psychologists is concerned—the average person can be forgiven for having it firmly lodged in his mind, for in literally hundreds of movies, TV and radio plays, books and novels this is the picture that has been painted. One of the first tasks of this section will be to attempt to straighten out some of these misconceptions so that a clearer idea of the nature of psychology can be given. While the mysterious and, unfortunately, rather glamorous aspect of psychology that concerns itself with mental illness and its treatment is certainly one facet of the topic, there is a good deal more to it than that. Furthermore, the part of psychology which deals not with the abnormal but with the strictly *normal* brain is the area which has best repaid scientific study and, as we hope to show, which has uncovered the most exciting raw material.

This section, therefore, begins with a clarification of the role of the psychologist, and follows with a brief introduction to his principal fields of study—the brain and human behaviour. After this we take in turn the four main areas of study which assist him in his quest for an understanding of human nature. These are Perception, Learning and Memory, Motivation, and finally Personality and Thinking.

One of the main sources of confusion in people's minds arises from puzzlement over the distinction between four commonly used words which, while differing in meaning in important respects, are almost invariably lumped together as one. These are (1) Psychiatry, (2) Psychoanalysis, (3) Psychotherapy, and (4) Psychology. The words do look and sound rather similar but it is not difficult, once the right definitions have been given, to sort the four clearly out in one's mind. Let's take psychiatry first.

(1) **Psychiatry** is the art of *treating* mental diseases or illnesses by medical means and it is a specialist branch of medicine, entered through the medical profession and taught at hospitals or universities. A psychiatrist therefore is quite invariably a doctor of medicine with ordinary medical degrees but with a postgraduate training in mental illness and its treatment. No one may call himself a psychiatrist unless so qualified, and no one may prescribe drugs or surgery in treating mentally sick individuals unless he is medically qualified. There is an important point of issue here, for in England, and many other countries, people not trained as psychiatrists may nevertheless diagnose and treat mental illnesses—provided that they do not use drugs or surgery to do so.

(2) **Psychoanalysis** is a particular form of examination or diagnosis of an individual's mental state based on the theories of the mind and personality advanced by Sigmund Freud and his colleagues or followers, and the reader may like to turn to the entry on the subject in **Section J**. An interesting feature of psychoanalysis is that, unlike psychiatry, it may be practised without medical or academic qualifications on the part of the analyst. A special training analysis at a recognised institute is normally undertaken by the would-be practitioner, however this is not normally made available to individuals unqualified in medicine or psychology.

(3) **Psychotherapy** is the practice of treating mental diseases or illnesses by more or less *any* means. Thus, strictly speaking, both the psychiatrist and the psychoanalyst are psychotherapists—as are any other individuals using reputable methods who offer therapy for the mind. Once again notice that this implies that one may call oneself a psychotherapist irrespective of whether one has medical or academic qualifications, and it is a word that tends to be adopted, with impunity, by a good many "quacks" and charlatans who can of course do fearful damage in this tricky area.

(4) **Psychology** is literally the study of the mind (or soul) but its area has broadened somewhat in the last century as we have learned that one cannot consider the mind as totally isolated from the body, and it now includes the study of human personality and behaviour. Psychologists also study the behaviour and brain of animals wherever such studies throw light on human behaviour. It is important to realise that psychologists are first and foremost trained as scientists rather than as medical experts and do not necessarily take much interest in abnormalities of the brain and mental processes. Those who do, tend to take postgraduate training in what is known as "clinical psychology," and may add to their knowledge by undergoing training in psychoanalysis.

It is obvious that there is a good deal of overlap between these four aspects of the topic and in the following section we shall be entering the territory of psychiatry and psychoanalysis to some extent, but mainly concerning ourselves with psychology—the science and study of the human mind, personality, and behaviour.

1. The Brain.

From the moment of our birth and emergence from the security of the womb our body is controlled and dominated by a single but complex organ, a library, switchboard, signal-box, com-

puter, and many other things all rolled into one—the brain (*see* F37(2), P46). Very properly encased in a hard shell of bone and equipped with instruments for detecting food or danger at a distance—eyes, ears, etc.—the brain matures slowly, unlike other bodily organs, reaching its peak of efficiency and potential approximately 18 years after birth. From then onwards, slowly and almost immeasurably at first but with remorseless steadiness, it slides into decline. Its proper functioning determines the "normality" of the behaviour of the individual and the part he can play in society, its efficiency determines to some extent his intelligence and his ability to compete, its storage capacity and information retrieval system, his potential to learn and remember. In addition its computing power determines his creativity and is the primary function which distinguishes between the mature human being and the other animals on earth. No organ or complex of organs is guarded and shielded so carefully.

The brain is the main focus of interest for the psychologist, for there can be little doubt that the key to the understanding of human personality and behaviour lies locked up within it. Its complexity of course is daunting, but thanks to physiological and anatomical studies it is possible to get at least a general idea of what's going on. In the first place the brain acts as the principal co-ordinator of messages coming in from the various sense organs, and then as the dispatch point for the appropriate responses. This co-ordinating centre is easily best developed in man, and is present in most of the "higher" animals. Simpler creatures, however, such as amoeba and certain tiny worms, get along without any important co-ordinator of nervous impulses and respond diffusely to changes in the environment—moving vaguely away from things that "annoy" or damage them and towards food or other "pleasant" things. Such animals are literally the slaves of their environment, incapable of setting up goals to achieve and with no facility for computing the consequences of any action. One important branch of the evolutionary tree shows a steady trend towards increasing brain size and, with it, freedom from this slavery.

In the second place the brain acts as the storehouse of information which the senses have gathered at some time in the individual's life. To us it may seem "obvious" that we have a memory—a device for looking at things that took place in the past—and indeed it is hard to imagine ourselves without one. However, a large number of creatures get by with only the most limited of memory systems, and some with none at all. Clearly a good deal must depend upon how long an animal is to live. If its life-span is to be brief, then it need not set aside much room to store information from its past. If it is to live for many years, survive in a changing and generally rather dangerous environment, and learn by its mistakes and its previous achievements, then this ability to refer back to the past is obviously essential. In human beings mechanisms of learning and memory are of vital importance and we will devote a good deal of this section to discussing the way in which psychologists study these.

The third primary function of the brain is to provide the computing and decision-making processes which dictate so much of human and higher animal behaviour. It is also, in the case of man, the centre of consciousness and at the same time that elusive faculty we call personality.

2. How Does the Brain Divide up its Functions?

Nowadays we rather take for granted that important things such as thinking, remembering, etc., are mediated through the brain and it comes as something of a shock to recall that early philosophers located the majority of such processes in the heart or the stomach! Even today, a good deal of controversy exists over exactly which part of the brain does what and, as we shall see when we discuss the contradictory experimental evidence later, there is even a suggestion that certain processes are dealt with by the brain *as a whole* rather than by some specific part. However, the picture is reasonably clear.

In the first place the brain is composed of a vast number of cells—the building blocks of all living systems—which in this case have become highly specialised and stretched out, rather like telephone lines. These are known as nerve or neural cells or, yet again, as neurones. They act as communication units, receiving electrical signals from other parts of the body. Comparative anatomists are able to trace the routes of whole chains of cells starting at, say, the finger tips and finishing up in a particular slab of the brain where such tactile messages are gathered and interpreted. On the whole messages from the eyes tend to finish up in the back of the brain, or occipital lobes; messages from the ears, nose, etc., on the side, or temporal lobes. In the front exists a large chunk of nervous tissue with a rather mysterious function inasmuch as it seems to be more directly related to the personality and mood of its owner than to any of his senses. In addition there are parts of the brain concerned more with output than input—the so-called motor areas which dispatch the signals commanding various parts of the body to move. Finally there are the parts principally involved in the storage of information, memory, etc.

All these areas we have been talking about up till now are known as the cerebral cortex and they are located on the outer surface of the brain itself —*i.e.*, right up against the inside of the skull. You should by now have gathered that the cortex deals largely with psychological factors closely tied up with consciousness and awareness—seeing, hearing, thinking, remembering, etc. This ties in rather nicely with its alternative name, the neocortex (or new tissue), for in evolutionary terms this part of the brain is "new." In general, the closer that an animal species approximates to man, the greater the proportion of its brain is assigned to neocortex, and the more the particular animal is capable of independent, deliberate and purposeful activity.

Tucked in beneath the cerebral cortex, growing out of the spinal cord, are the so-called lower centres—the old brain. Here in a number of specialised blocks are located the control centres which deal with the most automatic (but no less important) bodily functions such as cardiac activity, respiration, temperature, etc., and which it is unnecessary or inconvenient to keep under conscious control. Damage or injury to these centres is generally very serious, whereas damage to the outer layer of the brain, even when extensive, can have surprisingly little effect on the individual's way of life.

To sum up, we note that the brain is divided into two major functional areas in evolutionary terms—the old and the new. The former largely deals with the vital automatic processes, and the latter with the receiving and interpreting of sensory input and the decision-making processes which guide our interaction with the outside world. Clearly this is an enormously simplified picture (specific aspects of this topic are dealt with in greater detail later) and the brain and central nervous system (CNS) is complicated almost beyond description, with much of its mechanics and rules of operation still poorly understood. How then can one set out to study it properly and unravel its secrets?

3. Methods of Studying the Brain.

Psychologists and physiologists favour many approaches to finding out how the brain works, and while it won't be possible to look at them all in this section it will be worthwhile spending a bit of time on some of the most important lines of attack. These can be classed under the headings (1) comparative anatomy, (2) surgical tissue destruction, (3) electro-encephalography, (4) microelectrode recording, (5) biochemical analysis, (6) behavioural research, and (7) introspection. Some of these are really only possible with animals as the experimental subjects, and others are more suited for research on human beings.

(1) *Comparative Anatomy.*

This is perhaps the most obvious and logical method of all, but it has one serious and insurmountable drawback. Suppose that one wanted

to find out how a motor-car engine worked and that one had no prior knowledge of its operation but knew what one looked like from the outside. Failing instruction booklets or advice from motor mechanics, the best method might seem to be to get hold of a complete engine and take it apart to examine its components. Given enough skill one might even be able to put it back together again. The chances are that with a relatively simple device, such as an automobile engine, an intelligent person would begin to see the principles of operation. However, until he had actually watched it at work and studied the effect of, say, depressing the accelerator or pulling out the choke, his comprehension of the device might be limited and he could well come to some funny conclusions about its function and operating habits. This approach is essentially that of the comparative anatomist who sets out to study the brain by examining a dead specimen, peering at it through a microscope, cutting out bits here and there and hoping to work out what each section contributes to the whole. Unfortunately, whereas the average motor-car engine probably contains a maximum of about 1,000 discrete and separate components, some of which are rather large and "obvious," the brain contains a conservative minimum of about *a thousand million* neurones or nerve cells and no large and obvious "moving parts" to give the anatomist useful clues. It is little wonder therefore that while students of the brain adopting post mortem dissection have, in the course of the last few centuries, acquired a pretty clear picture of the way in which the brain is laid out—an anatomical atlas so to speak—most of the principles of cerebral operation are still more or less unknown. One of the great drawbacks of this system, as you will probably have guessed, is the fact that anatomical dissection and analysis can only be done in the dead animal.

(2) *Surgical Tissue Destruction.*

To return to our rather inexact analogy with the motor-car engine, let us assume that our investigator finds himself with a working, running engine to play with. Let us also assume that he has already made himself pretty familiar with the anatomy of the "dead" engine and has perhaps formed some hypotheses as to what certain parts of it do. For example, he might have a suspicion that the carburettor and the sparking plugs were particularly important, or that a key to the complete device working was that the pistons should move up and down in the cylinders. One of the first things he might do would be to systematically remove what he considered to be important parts of the engine and note how its performance was effected. Using this technique of selective removal he might soon begin to confirm or reject his hunches and a gradual comprehension of the function and capabilities of the engine would build up in his mind. He might find that whereas the removal of one sparking plug did not stop the engine, it would lower its pulling power. Removal of the carburettor in toto would be calamitous, while twiddling with it might have unpredictable effects, making it run better or worse. On the other hand, filing bits off the iron cylinder block would make no difference whatsoever. Once again the psychophysiologist is faced with something immensely more complex when he studies the brain, but there is nevertheless obviously something to be gained by adopting a similar procedure with the working or living system. The systematic removal or destruction of parts of cerebral tissue has, in fact, been one of the most rewarding approaches adopted by brain scientists, though there are naturally severe limitations to the technique. In the first place such surgery cannot be performed on human beings, except where it is a necessary feature of therapeutic brain surgery (*e.g.*, as when removing a brain tumour) and can only be justified in living animals in the interest of serious and clearly defined scientific research. (Despite the assumptions of anti-vivisectionists, no reputable scientist enjoys performing experimental surgery on living animals and these are always conducted in such a way as to cause the creature as little distress and suffering as possible.) In the second place, the very act of surgery itself probably introduces side-effects which serve to complicate the picture. However, this technique, when skilfully used, has led to some informative experiments.

(3) *Electroencephalography.*

As we have said earlier, the principal building blocks of the brain are the neurones, specialised cells devoted to the transmission of information from one part of the body to the other. This transmission is effected by a change in the electrical potential of the cell along its long stem. The main bodies of cells tend to be pressed up against one another and when a change in potential occurs in one, this tends to trigger off a similar response in a neighbouring cell at a junction point known as a *synapse*. Incidentally, the long stems of the cells (which may be a yard or more in length in certain parts of the body) are covered by an insulating sheath which prevents the electrical "message" leaking out en route and which makes them strangely similar to the kind of electrical wires and cables we use in telecommunications. With a thousand million cells jammed up together in the head, all of them propagating electrical signals in one way or another, it should not surprise anyone to learn that sensitive recording devices can be used to get a picture of the overall electrical activity going on in the brain. Studies of this type (electroencephalography, or EEG for short) couldn't begin until suitable recording machines had been developed and thus, although scientists had been pretty confident that the brain was a potent source of electrical energy since the middle of the 19th cent., it wasn't until the 1920s that anyone was able to get a readable picture of this. The pioneers in this technique were the physiologists Berger and Adrian, who attached little electrodes to the outside of the human scalp and by hooking these up to amplifiers and then to special recording pens were able to get a kind of plot of the electrical activity going on within. To their surprise what emerged was not just a meaningless hodge-podge of electrical "noise" but rather a series of precise and elegant rhythms, the frequency and amplitude of these depending upon the part of the brain where the electrodes were applied, and also—most excitingly—on the individual's mental state at the time of the recording. As time has passed and recording technology has advanced, an immense amount of data has been gathered on these so-called brain waves, and while it is true to say that the high hopes of the pioneers who believed that they were about to unravel the brain's mysteries almost overnight with this technique have not been realised, the EEG has proved its worth in more ways than one. In medicine, for example, certain disruptions of the "normal" brain wave pattern can give clear indications to the expert of the presence of epilepsy or determine the site of otherwise totally inaccessible brain tumours. The EEG can also be enormously useful in evaluating the effectiveness and mode of operation of new drugs and is helping in our understanding of the nature of sleep—the EEG of a sleeping person differs significantly from that of a waking one. Curiously one of the most promising-looking of the many rhythms which the brain emits—and one of the first discovered by the English scientist Adrian, the so-called alpha rhythm, has turned out to be one of the most disappointing. The alpha rhythm, which is generally picked up by electrodes attached to the back of the head (over the occipital or visual cortex), is a beautifully neat and stable wave of about 14 cycles per second frequency. It is present when the individual is relaxed and has his eyes closed. Opening the eyes and looking around, or alternatively keeping them closed and doing a bit of mental arithmetic, causes the rhythm to disappear, and the hypothesis was soon advanced that alpha was a reliable index of the rather abstract mental state known as "attention." Unfortunately for this convenient idea, on further study it was found that the rhythm did not always behave as it should, sometimes doing exactly the opposite to what was expected of it. Furthermore about one in ten otherwise normal individuals show no alpha rhythm at all. The picture has been complicated even further by the publication in 1973 of a book *The Origin of the Alpha Rhythm*. In

this the author, Dr. Olof Lippold of University College, London, advances the argument that alpha rhythm in fact reflects physiological tremor of the eye muscles, and therefore has very little to do with internal cerebral states. The presence of abundant alpha in the EEG, Lippold argues, is more likely to be evidence of poor vision than any special capacity to control one's attention. It's fair to say that Lippold's views are still highly controversial, but it should equally be clear that the simple view that brain waves denote complex internal processes is by no means established. All these drawbacks aside the EEG is still one of the best ways of getting some kind of index as to what is going on inside the head of a human or animal, without resorting to surgery or interfering seriously with normal thought processes.

(4) *Microelectrode Recording.*

For all practical purposes the record obtained by the EEG is a gross, overall view of the brain at work. The waves and rhythms encountered must, at the least, represent the sum of the activity of literally hundreds of thousands of neural cells, presumably firing more or less in synchrony. Going back once more to the motor-car analogy, the EEG could be likened to a garage mechanic listening with a stethoscope to the pulsing of an engine when running at high speed. Changes of speed, adjustments in carburation of timing, etc., would give characteristically different running sounds, but little if anything could be deduced about the state of activity of an individual component unless it were a very large one. Much the same limitations, only on a gigantic scale, surround the use of the EEG as a device for measuring specific aspects of brain activity. Quite recently, however, an interesting technological development has occurred which allows a more precise and delicate analysis of cortical cell firing to be undertaken—in fact to allow even the output from a single neural cell to be monitored. This technique involves the use of what are known as microelectrodes, tiny slivers of metal, thousandths of an inch in diameter, which when in contact with an electrical source—in this instance the body of a nerve cell or neurone—transmit a pulse of electricity to an amplifier and recording apparatus. We shall discuss the remarkable findings which have come from experiments of this kind later in the section on "Perception." Microelectrode techniques, incidentally, can on occasions be used with human subjects. In such cases, naturally the opportunity arises when an individual is undergoing brain surgery for, say, the removal of a cerebral tumour. In these circumstances, with the patient's permission, the surgeon may perform experiments to study single cell responses with results which have been of great interest.

(5) *Biochemical Analysis.*

Scientists have recently shown increasing interest in the microstructure of cerebral tissue, not just the neural cell but in its basic constituents—in other words at the molecular level. Clearly there is not much hope or point in trying to record the behaviour of molecules by electrode recording or even by microscopic visual analysis, so some other method must be found if one is concerned with this level of analysis at all. This is where the psychologist teams with the biochemist—an example of the kind of interdisciplinary approach which is becoming common in brain research. As with much of the chemical analysis performed in other fields, scientists discover the nature of the substance they are examining by observing its behaviour when mixed with other chemicals or compounds. Crudely speaking, one mixes the unknown substance with some known chemical and simply watches what happens, the reaction which follows giving clues as to the nature of the chemical under study. Now in the case of the brain or the constituents of neurones, it is obvious that one is dealing with more than one single substance so the first problem is how to separate the constituents in order to study them individually. To achieve this biochemists use a number of techniques such as chemical separation simple heating, and even whirling the material round at great speeds in centrifuges. The biochemical approach to brain research is a bit too complicated to deal with in detail here, but in the view of many it is one of the most promising avenues in this field.

(6) *Behavioural Research.*

Psychologists are interested not merely in the structure of the brain of humans and animals but also of course in their behaviour. By behaviour one means the way in which the individual interacts with its environment and its reasons for doing so. A study of what, when, and how a creature does something can tell one a good deal about the rules that govern behaviour. The way in which a bird builds its nest, a cat rears its kittens, a dog threatens another dog, frequently follow set patterns and presumably have something to do with the way in which at least a part of its brain is organised. Careful study of such behavioural patterns even allows one to make certain predictions about what an animal will do next in a given set of circumstances—and once one is able to predict accurately one has generally discovered something important. Studying animals (or people) " in the wild " is easier said than done and tends to be frustrating because of their tendency to do unpredictable things and their general disinclination to perform to order. Furthermore the range of behaviour that one can study by such methods is limited to the so-called " instinctive " actions which are frequently simple in function and execution. The alternative is to confine the animal in a laboratory and observe its reactions to an experimentally controlled environment. In this way one can study its learning and memory processes, its sensory mechanisms, its intelligence and capacity to " reason," its behaviour under conditions of stress, its preference for various foods, etc., etc. Behavioural research of this kind has turned out to be almost the most important method employed by psychologists in their attempt to understand the brain.

(7) *Introspection.*

The oldest and perhaps most obvious method of studying the brain was simply to think about it! This was the method adopted by early philosophers who believed that if one was sufficiently logical and intelligent one could work out the solution to practically anything. Unfortunately, while the brain, mind, etc., might seem to be an ideal subject for its own thought processes, this method of analysis—known as introspection—just doesn't seem to work in the way that it should. The principal problem is that much of the brain's activities are exceedingly rapid and automatic, as anyone can demonstrate for themselves. For example, turn your head and look at an object on the wall. It will be " perceived " and recognised apparently instantaneously. Even if you can detect a faint lag between the act of inspection and the act of *perception*, it is quite impossible to describe the steps or stages in the process. Much the same applies to other important mental faculties. One cannot, merely by thinking about it, say how one actually *learns* something, or how one calls an item up from memory. It was realising the relative hopelessness of this quest which led philosophers interested in the brain to convert themselves, in the middle part of the 19th cent., into psychologists and adopt an experimental rather than an intellectual approach to the problem. However, it should be equally clear (though many psychologists seem to have forgotten this) that there is a whole world of material which does not seem to make itself available to any of the experimental approaches (1–6) which we have described above. The study of language itself is a good example, being part of our mental life and thus of great interest. Similarly, certain features of abnormal psychology ranging from the bizarre thought processes of schizophrenics to the near-mystical states of mind reported by artists and poets, or the distortions of perception and personality induced by the hallucinogenic drugs, are central to the topic of psychology and are clearly only approached in the first

instance through some measure of introspection. What too of the raw material of psychoanalysis and the rich glimpse of the interior of our minds granted us through our dreams? These are merely a few examples to highlight a single point that—when studying the brain we should not ignore the mind's power to look in on itself.

This concludes our condensed survey of some of the principal methods used by psychologists and their colleagues in attempting to get to grips with their exciting and challenging field. The reader may have been surprised by a number of things, one of which must surely be how very much wider is the territory covered by psychology than is commonly believed.

4. What do Psychologists Study?

We now come to examine the main areas making up the subject matter of psychology. There are all kinds of ways of breaking this material down and as the topic is so immense (and enlarging quite rapidly) one or two important aspects will have to be left aside. We shall only refer in passing, for example, to the important sub-sections of Child Psychology, Industrial Psychology, and Ergonomics, for these need to be treated separately if they are to be properly understood. Furthermore, much of the material inherent in Sociology will have to be passed over for similar reasons. The reader will also notice some overlap between the various headings which merely confirms what one ought to suspect—that in studying human beings or living animals, it is really impossible to segment the approach completely. A person is an entity and something more than the sum of his various parts.

For the purposes of this Introduction we will consider Psychology as constituting principally the study of four major factors—

(1) Perception, which includes the study of the way information is gathered by the brain and how it is interpreted;

(2) Learning and Memory, which deals with the way the information is stored once it has been gathered and, subsequently, how it is retrieved when wanted;

(3) Motivation, which includes the vital topic of why a human or animal interacts with its environment and why it does one thing rather than another; and

(4) Personality and Thinking, which tackles the abstruse problems concerned with consciousness, self-awareness, and, naturally, disorders of both.

Anyone reading this Introduction seriously will find that in acquiring his first formal background in Psychology he will also have to think at times like a physiologist, a philosopher, an anthropologist, and a good experimental scientist, all rolled into one. This will turn out to be less complicated than one might imagine.

II. PERCEPTION.

(a) Information Gathering and Information Decoding.

The topic of perception itself breaks down into two significantly different headings and it is very important to comprehend the distinction between the two before going any further. These are the processes of *information gathering* and *information decoding*. If these words seem a bit bothersome, they need not be. Information has a meaning in science rather broader than details of train times or facts from history, and it really deals with the influence of one object, person, or thing, on another. For example, when you look at the sun or a bright light, photons from the luminous object strike the retina or sensitive layer at the back of the eye. As the result of this the retina changes its state slightly and in due course passes signals back to the brain. Now the interaction between the sun and the retina, odd though it may seem at first, constitutes an exchange of information, and when the message finally reaches the brain and the sun is recognised for what it is, the information has flowed all the way from sun to brain. If this appears to be an odd use of the word "information," then this is probably because one has tended to think that information can only be conveyed through words or numbers and "meaningful" conversations. The more one considers this limited point of view, however, the less reasonable it seems. If one looks at a painting, which contains neither numbers nor words, but a picture of, say, a ship at sea, then most people will agree that it is conveying information (the artist originating it whenever he painted the picture). In fact we can use this analogy to add that the painting itself can be looked upon as a kind of information store since the artist who set the whole process going could easily be dead and gone, and yet his message continues to be conveyed. If one no longer feels it inappropriate to talk of the sun as an emmitter of information to the eye, then we have made a major advance and can move on into the meat of this sub-section. It is really important to get some grasp of the scientific use of words like information and information storage for they will pop up time and time again and one can make nothing of modern psychology without them. Incidentally, when we spoke of the retina sending signals up to the brain where the sun was "recognised," it should be remembered that what reaches the brain is not a kind of miniature sun but rather a pattern of impulses which need to be interpreted. This interpretation we call information decoding and it is the second important factor in perception which we will come to shortly. But first, how is the information received and gathered?

(b) The Five Senses.

Simple creatures, such as amoeba, react in a vague, generalised way to objects in their environment. The reason for this is that they have no specialised equipment to allow them to detect what is taking place, or about to take place, around them, and no computing centre capable of selecting alternative modes of behaviour. As we ascend the evolutionary scale from jellyfish to worms and up through reptiles, mammals, birds, etc., we note increasing specialisation of the body's cells, the development of devices capable of scanning the external environment and increasingly complex co-ordinating nervous centres (brains). By the time we reach Man and other advanced animals, the individual is not merely reacting to his environment but consciously aware of its flux, able to predict many of its changes before they can effect his body physically, and frequently manipulating it significantly to suit his own ends. This immense versatility is dependent upon information from the environment being fed into the nervous system for processing, and the devices which the body has developed to gather this information are known as the senses—vision, hearing, touch, taste, and smell—roughly in order of importance. Without these senses, the interface between the central nervous system and the world outside, a living creature is nothing more than a helpless vegetable, incapable of survival. For this reason if we are to get anywhere with understanding the operation of the brain we will need to know a fair bit about the sense organs that feed it. We shall spend most time on the two most important—vision and audition.

(c) The Eye.

Perhaps the most useful information from the brain's point of view would be that which concerns the detection of food or a mate at a distance or, of course, the presence of danger in the form of a predator. Consequently, the most vital and remarkably developed of our sense organs are our eyes, which are geared to detecting radiation over a frequency range which we call "light." For those who like this kind of detail, the actual spectrum detected by the eye covers light frequencies whose wavelengths range from about 380 nm to about 720 nm (1 nm = 10^{-9}m). All this means is that the distance from peak to peak of the waves which constitute the light is a very small amount indeed—far less than a thousandth

of a millimetre in fact. Note, however, that not only can the eye detect the 380 nm and the 720 nm waves quite easily but it can also discriminate between them and a whole lot of other wavelengths in between as well. In fact we call the 380 nm waves "violet," the 720 nm "red," those of about 500 nm "green," etc. Remember the minute wavelengths involved and you will appreciate that whichever part of the eye handles this kind of information must be very sensitive indeed. This fabulous bit of equipment, one of the most remarkable of all biological systems, is called the retina.

The Retina.

Situated in a layer at the back of the eye the retina is a kind of screen on to which rays of light are focused by the lens after having passed through a window at the front, which is called the cornea. The question now arises as to how the retina detects the light rays and how it then signals the relevant information on to the brain. There are two ways of answering this question, one very complicated and reasonably accurate, the other quite simple and slightly less accurate. We'll choose the simpler and lose a bit of accuracy without worrying too much.

The principle employed is that of energy absorption. The retina is a densely packed mass of neural cells whose speciality is that they contain light-sensitive substances known as "pigments." These substances change their state rapidly when the photons from a light source strike them, and this change, which is really a high-speed chemical reaction, acts as the trigger which "fires" the cell. This in turn sends a pulse of electrical activity up the neurone's long stem in the direction of the brain. After it has fired, the cell then requires a brief period to recover its normal state and for the minute portion of bleached pigment to regenerate, during which time (known as the refractory period) it will not fire again. Multiply all this by one hundred million, which is the approximate number of cells in the retina, and you will get some idea of the frenzied activity contributing to the process of vision. To complicate matters there are at least two major types of visual receptors, the cones and the rods. To go into their infrastructure in detail is really the province of physiology, but it is necessary to know something about their prime function which is that the cones tend to handle the higher levels of luminance met in daytime and also mediate colour vision, while the rods, which are far more sensitive, tend to come into life in the dusk or dark. The shift from cone to rod vision, which, like most of the body's basic functions, is entirely automatic, is something we all experience regularly in our daily life. Walk out of the sun into a dark room and for a moment one is "blinded." Walk out of a dark room into the sun and again one is "blinded." Actually all that is happening is that the visual system is having to shift from one set of receptors to another and when the change is extreme and rapid, the lag in the switchover is dramatically apparent.

Colour Vision.

Psychologists have known for a long time that the cones, which tend to be packed in the centre or "more useful" part of the retina, have something to do with colour vision, but just how they do this job has been a matter of much debate and argument. One of the most likely bets would seem to be that particular types of cone are equipped with particular types of pigment, one sensitive to light in the "red" range, another to light in the "yellow," another in the "blue," etc. But how many types of cone would one need, therefore, to get the kind of colour vision we enjoy? Would one have a separate type for each subtle shade of hue for example? When thinking such things out scientists always try to see first if they can get by with the smallest possible number of hypothetical elements, and only bring in extra mechanisms when they are absolutely stumped—a principle known as "Occam's razor" and one universally revered in science and philosophy. With this in mind and with a bit of ingenuity, the general view at the moment is that three separate types of colour receptor are all that are needed to account for human colour vision; this is known as the trichromatic theory which is all we need to know about it for the purposes of this article. But just to show how complicated things are, and yet how interesting for this very reason, we will pause to look at some experiments in human colour vision which show that no matter how neat and simple an explanation is in psychology, there is always a joker hiding in the pack.

Some Experiments in Colour Vision.

To understand these experiments, which were performed by a Swiss psychologist, Dr. Ivo Kohler, we need to know a little bit about the phenomena known as after-images. This information will come in handy again a little later on when we talk about after-images in a slightly different context. You may have observed that if you look at a bright light for longer than a second or two, when you close your eyes you see a continuing image of the object which may persist for quite a while and exhibit a nice range of rather bright colour changes. If you haven't observed this, then you can experiment yourself by just fixing with one eye on the filament of an electric light bulb—not too close to the eye. Count five slowly as you do so, then close your eyes and observe. (Don't do this with the sun, by the way, as it could be dangerous.) Now the important point at this stage is the changes in colour you will see taking place, which are generally believed to occur because the bright light has slightly overbleached the retinal pigments and they are taking longer than usual to recover. In the process of recovering they continue to send signals to the brain, which interprets this information as if there was still a light source present and thus the bulb filament is "seen" long after it has really gone. The colour changes themselves are probably due to the fact that some pigments regenerate a bit more quickly than others and thus a sequence of colours is perceived. All this involves lights of greater than average intensity and the question is whether one could get "after-images" with low intensity objects looked at for a long time. The answer is yes, and for anyone who hasn't noticed this before, another simple experiment can be tried. Take a book with a brightish colour binding—say red. Fix on it with one eye, trying to keep your head and eye as still as possible and hold it for about one minute. Now, turn the head away from the book and look at a blank, light wall or other flat surface. What one will see is a rather amorphous image of the book, but coloured green, which will linger for about half a minute before it fades away. This is another version of the first trick, with the after-image being due to the bleaching of the red pigment, and to various other changes that follow in its wake. Now the after-image, as we have noted, soon fades away and no doubt this has something to do with the intensity of the original stimulus. But what would happen if, instead of merely exposing oneself to the colour for a minute or two, one extended the time period to an hour, or a day, or a week, or even longer? This is exactly the question that Kohler set out to answer. To get over the problem of how one could possibly go on looking at something for hours or days on end, he decided on the simple expedient of wearing tinted spectacles and going about his business as usual. For the first experiment, using pink spectacles, he made a number of interesting discoveries. Number one was that although for the first few hours in his experiment the world took on a rosy hue, before the first day was over things were nearly back to normal. After a few days there was no longer any suggestion of a more than normal amount of pink about and his vision appeared to be unaffected—even though, of course, all light was being filtered through the red lenses and thus inevitably tinted. Discovery number two came when he finally took the lenses off to find the whole world tinged with green—the so-called complementary colour of red—a tint which remained for days! His next experiment, apart from doing the whole thing over again with a different set of colours—blue lenses providing a yellow world, green a red one, etc.—was to wear spectacles with one lens

red and the other green. This time the position was more complicated. If he closed his right eye, which had the red filter in front of it, then he saw green through the other lens and vice versa. With both eyes open, however, the two colours would "mix" in his brain and the world appeared through a kind of bluey haze. At this point you might care to try to predict what the scientist found when, after a few weeks of this and after all the colour had washed out, he finally removed the spectacles. In the first place, if he looked at the world through both eyes he saw the complementary to blue (which is yellow) but if he looked through either of his eyes singly he saw the world tinted with the appropriate complementary colour, red or green. Once again the new tints took some time to disperse. All this of course, while exceedingly interesting, could still be reasonably explained on the theory of pigments bleaching away due to long exposure and taking some time to regenerate. Unfortunately for this simple idea, but fortunately for people who like problems, Kohler's next experiment produced a surprise result. For this he had the ingenious idea of segmenting his spectacles so that the right half of each lens was tinted red, the left half green. The position now was that if the wearer looked to the *right* with *both* eyes he saw a red-tinted world, if to the *left* a green-tinted one. Looking straight ahead produced a muddling fusion of both colours. In due course, as one might predict, all spurious colours washed out wherever one was looking. Now came the surprise. On removal of the spectacles Kohler found that when he looked ahead he saw the complementary "fused" colour, but when he looked to the right he saw the complementary of red, which was green. When he looked to the left he saw the complementary of green, which was red. To work out why this was surprising one must think about what was happening in the retina. In the early experiments, with the whole of the right visual field tinted red, say, the persisting perception of the green after-image was felt to be due to some changes in the pigmentation of the cells in the retina. But clearly this will not do in the final experiment, for in this case the same areas of retina seem to be doing two different things. After the glasses had been removed, when the subject gazed to the right he saw a green field and one might assume that this was because the pigment had been changed by overstimulation. But how could this account for the fact that when the subject turned his eyes to the left there was a change of perceived colour to red? Clearly the pigment itself couldn't have changed in that time, nor could it change back when the eyes reverted to the left. Obviously, quite contrary to what one might expect, the colour changes were dependent, in this case, not on the state of the retina but rather on the direction of gaze!

No one has satisfactorily explained Kohler's intriguing results to date, but they do suggest one important point which one is always in danger of neglecting in psychology—that a living organism is not just a collection of parts acting independently of each other. In the drastic situation of wearing tinted lenses for days, or even weeks, changes were evidently taking place not just in the retina of the eye, but also in higher centres of the brain.

More About the Rods and Cones.

Returning briefly to the retina and its constituent cells we might just take a closer look at the rods which, you will recall, come largely into play in conditions of poor luminance.

The extraordinary sensitivity of the rods is the most interesting thing about them. Unlike the cones, which need the brightness of daylight to do them justice, one single rod will be triggered into action by light whose energy is as low as 100 aJ (1 aJ = 10^{-18} J), and if that is a value which has no meaning one can get a graphic idea of this sensitivity when one learns that in total blackness the eye could detect the light of a single candle five miles away! Put another way, the amount of kinetic energy used in lifting a pea only two cm would, if converted to light energy, be enough to give a brief sensation of light to every person that has ever lived on earth! The clustering of cones in the centre of the retina, the fovea, has been mentioned and the rods consequently tend to be scattered around in the periphery. You can detect this geographical distribution yourself by noticing that whereas in daytime your vision is much better directly in front of you, in very dim light you will be able to see objects on the edge of your visual field rather better. You might also care to note how the periphery of the retina, populated largely by rods and devoid of cones, is remarkably insensitive to colour. Offhand one gets the impression that the whole of one's visual field is richly endowed with colour, but this is far from true. A simple experiment will demonstrate this. Fix, with one eye closed, on a predetermined spot—a mark on a piece of paper will do. Then, slowly bring into your field of vision from the side a small piece of coloured paper drawing it closer and closer to the central spot. Now if you can manage to keep your eye really still and maintain fixation despite the tendency to peek at the incoming paper, you will be surprised how far in the latter will have to be before you can detect its colour with certainty. Try the experiment again with another colour and note that it may be recognised earlier or later. In this way it is possible to plot a simple map of one's own retina, defining the boundaries of the colour sensitive areas and nicely illustrating the division of retinal receptors into two distinct types with different jobs to do—the rods and the cones.

(d) Perception as a Dynamic Process.

Everything we have said in this particular section has reinforced the idea that creatures with complex brains are something far more than automata responding blindly to changes in the environment. Information fed in through the eyes, etc., is processed in some way by the brain, or "decoded," as we put it earlier. In fact it is this business of decoding and the possible mechanisms which help to achieve it that interest psychologists more than the raw details as to how the senses actually gather the information in the first place. Nevertheless until relatively recently there was a school of thought in psychology that made desperate attempts to deny, or at least reduce, the role of a central integrating process, implying that animal and human behaviour could ultimately be reduced to a great mass of stimulus-response networks, triggering each other into action in a totally mechanical fashion. This "Behaviourist" school, as it was known, had more impact on theories of learning and we shall look at it more closely when we come to the appropriate section, but it also influenced the thinking of psychologists interested in perception. The trouble with this point of view is that it is so obviously inadequate to explain the rich material of perceptual experience. One has only to think of the visual illusions that are experienced when information "correctly" relayed from the eye is "misunderstood" or incorrectly "decoded" in the brain itself. Clearly it is enormously interesting that all human beings fall prey to illusions, for it suggests that some common mechanism exists which is causing them.

The Gestalt Approach to Perception.

Among the first people to take this up as a general principle and use it as a frontal assault on the Behaviourist view was the so-called "Gestalt school" of psychology, founded in the early part of the century by three talented psychologists, Kurt Koffka, Wolfgang Kohler and Max Wertheimer. In point of fact they looked more closely at other common features or anomalies of perception than at visual illusions, for they believed that the introspective and experimental analysis of human perceptual experience allowed one to deduce the "laws of perceptual organisation" and that these laws must throw light on the fundamental operating procedures of the brain itself. A simple introduction to Gestalt theory is given in Section J so we will confine ourselves here to looking at a few of their more important ideas, most of which are still valid in modern psychology. The first was their insightful statement that in perception *the whole is something*

more than the sum of its parts. This principle is nicely illustrated by the fact that a series of dots drawn fairly close together in the shape of a ring are perceived as having a very definite " form "—*i.e.*, that of a circle—despite the fact that all one has actually put on a paper is a collection of dots. Dots are all that are perceived by the retina, and the signals passed up to the brain can only be those arising as the result of the dot stimuli. Look at such a picture, however, and one sees a circle. But where does this come from? From the brain say the Gestalt psychologists, pointing out that the whole (*i.e.* the perception of the circle) is something over and above the sum of its parts (*i.e.* a collection of points or dots). The same thing can be applied to lines, or practically any other shape, and can even apply in the auditory sense (a " tune " is something over and above a collection of separate notes played in sequence).

Gestalt Laws of Perceptual Organisation.

The Gestalt school argued that this was clear evidence for the existence of dynamic forces in the brain whose function was to mould or *structure* the information as it was fed in by the senses. Further examples of this structuring could be seen in other types of visual phenomena, and Koffka and his colleagues formulated a number of " laws of perceptual organisation " which they held were universal and also, probably, innate or " built into " the brain at birth. These laws are a bit too involved for us to discuss in detail but one or two are worth mentioning because the reader can conduct simple experiments for himself. The first, known as " Continuity," is a rather obvious one and similar to the example of a dotted circle that we had earlier. This states that a collection of dots arranged so that they form a " continuous " line, whether straight or curved, would tend to be perceived *as a unit.* In other words, structuring forces within the brain tend to act upon such dots causing them to be perceptually linked despite the fact that they have no true continuity in the physical sense. The age-old perception of the constellations in the sky, formed out of near random stellar patterns, is a good example of the law of " Continuity " in action. Another important law is that of " Similarity." To observe this in operation, scribble on a sheet of paper about twenty small crosses at random. Now, among these crosses again scribble down about 10 small circles. Look at the composite picture and you will probably note that the circles, more or less wherever they are, tend to stand out in isolation from the crosses—the law of " Similarity " in operation. Obvious? Maybe—but why *should* similar things stand out against a dissimilar background? Obviously some important factor in perception must be at work. Yet one more Gestalt " law," that of " Closure," is worth mentioning because its operation is easy to observe experimentally. Koffka and his colleagues believed that the perceptual organising system tended to dislike incomplete or partial figures and where possible would " close " them. This was particularly true, they argued, with neat, simple figures such as circles, triangles, etc. To illustrate this, draw a small neat circle on a piece of paper but leave a small gap in it, say about a tenth of its circumference. Now close your eyes and open them very briefly to give yourself a fleeting glimpse of the figure you have drawn. The chances are that what you will see is a circle—without the gap. Try this on someone else who doesn't know that there is a gap present and it will work even better. Now one might reasonably argue that one has missed the gap because one didn't have time to see it, but that's really no explanation as to why one should see a *complete* circle. The Gestalt argument is that in such fleeting glimpses, the law of Closure within the brain overrides the rather feeble information about the gap that comes up from the retina and the result is the gap just never gets perceived. The effect, incidentally, works for longer looks at patterns viewed in dim light.

A good deal of controversy surrounded the Gestalt approach to perception, much of which has died down in recent years as the Gestalt point of view has gradually fallen out of favour. One of the most controversial facets of the theory was the belief that the so-called laws were innate, or present at birth. In other words if one could somehow question a new-born baby and get a sensible answer out of it we would find that it too had its perceptions modified according to the Gestalt laws of Continuity, Closure, etc. And this brings us to the very interesting question of just what it is that babies can see at birth—if anything.

(e) Learning to See.

Anyone who has spent any time with very young babies will realise that their powers of perception are at best poorly developed. The mother may feel greatly flattered at being " recognised " with a smile, but the harsh facts are that a young baby will produce a charming smile for practically anything—even an absolutely horrific mask—that's placed in front of it. The psychologist William James (brother of the novelist Henry James) actually stated that the world of the newborn baby was a " buzzing, booming confusion "—in other words a mass of sensory data rushing up to the brain with nothing up there to interpret it. This is probably close to the truth—at least as far as human babies are concerned, for there is very good evidence that babies do not come into the world equipped with the ability to perceive the environment in the orderly, clear-cut way that adults do. Incidentally, this is not due to any deficiency in their visual system for the new-born's eyes are physiologically mature with at least the *potential* for detailed colour and pattern vision. What seems to be happening is that in the first few months, perhaps years of life, young humans literally have to *learn to perceive*, as the brain gradually acquires the power to integrate the information sent up by the senses, into a meaningful picture of the environment. There can be no better illustration of the vital distinction psychologists draw between vision (or audition for that matter) and the act of *perception.* One concerns itself with input, the other with its interpretation. Now with animals it is a different story—somewhat. Among the primates, chimpanzees, monkeys, etc., perception at birth is better than with humans but still pretty uncertain and the lower down the animal kingdom (this is called the phylogenetic scale) one goes, in general, the better the creature is equipped at its birth to perceive the environment. Look at it another way and say that the simpler the creature and the less well equipped with cerebral cortex, the more wiring or circuitry is built into it and carried over to every member of the species. This of course is what is meant by instinct—an inherited behaviour pattern or function of some kind which appears in every member of a species at birth. *See also* F38(1)

Instincts are very useful in one sense since the creature endowed with them doesn't have to learn the instinctive task and can perform it at birth (suckling is one of the few human instinctive reflexes). On the debit side, however, is the fact that one can't *unlearn* the instincts either, so that the more of them one has, the more likely they are to get one into trouble if one is a creature likely to change its environment in any radical way. Think, for example, how powerless human beings would be if they were subject to an instinctive desire to hibernate for six months at the onset of each winter. Clearly instincts are good for creatures with limited cerebral capacity, but a big handicap if one wants to respond in a flexible way to the world around one. The big question now is, does the ability to perceive develop as a natural consequence of the maturing brain, or is it dependent upon practice and experience?

Some Investigations.

If one takes kittens and brings them up in total darkness for, say, a month, on being subjected to the light they seem to have normal perception—pretty well equivalent to that of kittens normally brought up. However, if one extends the rearing-in-the-dark for a much longer period, say a year, then the young cat never seems to achieve normal vision on its introduction to a lighted world. Post mortem examination of the brain reveals that certain parts of the visual system seem to

have failed to develop in the normal way. Evidently there is a critical period, which when exceeded without visual experience, stultifies the brain so that normal perception can never be achieved. But what of humans? This may seem an impossible question to answer for how could one conduct the necessary experiment—*i.e.*, deprive new-born babies of light for up to a year—without outraging all moral and ethical values? In fact, by an odd and fortunate twist, the necessary data has come to us without the need to perform an impossible experiment. In the 1930s new techniques of surgery allowed the performance for the first time of an operation to graft the human cornea. This, you will recall, is the transparent window on the front of the eye which can, with age or disease, become clouded and opaque. Occasionally the cornea may be opaque at birth with the result that the individual can never achieve the perception of patterns or shapes. Because some light is getting through the milky window, however, he may be able to tell the difference between, say, periods of light and dark. Prior to the 1930s people afflicted with clouded corneas were consigned to a life of effective blindness—the more tragic because in all essentials they were frequently equipped with perfectly operating retinae, optic nerve, etc. With the development of corneal transplant surgery the picture dramatically changed and, while the operation is now usually performed at a relatively early age, there was an initial group of people in middle-age waiting to be treated who had *never had normal vision*. Realising that this provided a unique opportunity for an interesting observational study, the German psychologist Von Senden arranged to follow the progress of the patients with new corneas and record their reactions to the sight of objects which they had hitherto only heard described. Von Senden was set for some surprises—but nothing like the ones that he got. In the first place the newly-sighted patients, far from gazing round in wonder at the marvels of the visual world, were apparently totally incapable of making any sense out of it! This was not, incidentally, a mere failure to recognise subtle differences such as exist between people but a totally inability to tell the difference between most common, everyday objects. Showing the patients large simple drawings, such as a triangle and a square, naming them and then switching their relative position would totally confuse the patients. In order to tell the difference they would have to laboriously trace the outlines of each figure, carefully counting the corners. Notice that they could *see* the outlines, corners, etc.—their eyes were functioning properly—but they were unable to perceive the pattern. Their brains were simply not equipped to recognise shapes and, like young babies, they had to learn the whole process slowly and laboriously. Von Senden's second surprise came when he found that few of the patients seemed to find, at least in the early stages, the gift of sight at all welcome. Some, in fact, literally begged the doctors in the hospital to replace the bandages over their eyes! As with young babies, their visual world was indeed one of "buzzing, booming confusion" and it took some getting used to. There's a happy ending to Von Senden's story. All patients in due course acquired the ability to perceive, slowly at first but with increasing speed and confidence.

The moral of all this is clear, and once again emphasises all the points we have been trying to make about perception. The brain is a device designed to integrate information fed into it by its senses. In due course this integration becomes almost automatic, but this is reached only after a long period of training, which in humans occupies the greater part of infancy and early childhood. How much is actually "built into" human brains at birth in the field of perception? Probably very little, if Von Senden's work is accepted without reservation. Unfortunately there's some curious contradictory work to muddle the issue (as usual) and it concerns experiments with young babies performed by the psychologist J. J. Gibson. His strategy was to take infants and get them to crawl towards what he termed a "visual cliff." This consisted of a sheet of strong glass placed across a kind of trench or ditch in the laboratory, the bottom of which was lined with a chequer pattern. The children were tempted to cross the trench to come to their mother, this of course involving their venturing out over the glass sheet. Adults might naturally hesitate slightly, pondering perhaps the strength of the glass and the depth of the pit below it. Young babies would of course know nothing of the fragile nature of glass so should not be worried by that. Nor, if they were not equipped with proper pattern recognition mechanisms, should they be able to appreciate the "depth" of the pit or the nature of the visual "cliff" they would have to cross. Gibson found, however, that all children showed exceptional caution when reaching the "cliff" point, and many could not be tempted into apparently empty space. Common sense? Perhaps, but either they have the perceptual mechanism or they don't, and in this case it looks as though the perception of depth, and even some kind of appreciation of the gradients involved in the cliff were at least present in the babies capable of crawling. Does this contradict the work of Von Senden? Not necessarily—perhaps certain vital things (such as the ability to recognise a steep slope) are "instinctive" in humans, while matters such as the perception of patterns like faces, triangles, squares, etc., need to be learned.

(f) The Building Blocks of Perception.

To this point we have been considering (i) how the information is fed into the brain; and (ii) the evidence for the fact that dynamic integrating forces act on this information to mould it in specialised ways. We must now try to consider how this processing might take place. In other words what actually happens inside the brain when a particular pattern or shape is recognised?

Investigation of Individual Nerve Cells.

To get some insight into this we need to take a closer look at one of the latest techniques for studying the brain which we referred to earlier and which is known as microelectrode recording. The principle here is to insert an exceptionally fine electrode into the cortex of an anaesthetised animal, endeavour to place it against the body of a single neural cell and then, via a suitable amplifying system, record the pattern of electrical activity given off by the cell. This technique, which was developed in the 1950s, represents a significant advance over that of electroencephalography (the recording of brain waves from outside the head) inasmuch as instead of being faced with a rather vague pool of electrical activity, possibly coming from numerous cerebral sources, one is able to study the responses of what must surely be the brain's fundamental unit, the neural cell. Studied in this way the activity of a single cell is very interesting. Firstly cells appear to have no period of total inactivity—whether the creature is sleeping or waking and whether stimulated or not, single cells keep up a steady, periodic burst of firing at an average frequency of one burst every few seconds. This has acquired the name of "spontaneous activity," which is another way for saying that psychologists and physiologists don't know what causes it. In the normal, living brain therefore, even when the creature is in a totally relaxed state, millions of cells are bursting periodically into action, a continuous background of electrical noise. This presumably signals the presence of life itself for only with the death of the individual do the brain's cells cease their restless firing. When the animal is stimulated in some way, by light, noise, heat, cold, etc., then measurable changes take place. If the stimulus is visual, cells in the visual cortex of the brain burst into life, while those in areas subserving other senses remain at their spontaneous level. Introduce auditory stimuli, or mixtures of other stimuli and cells perk up in the appropriate areas of the brain. All this is very much as one might expect, backing up our knowledge that different sections of the cortex handle different tasks. But can one focus down rather more sharply? What happens if one studies the behaviour of cells within only one area of the cortex when different stimuli mediated by the same sense are fed in?

This experiment was first performed by the American physiologists, Hubel and Wiesel, with remarkable results. First, they located a cell in the visual cortex of the cat and began to record the output from it when the cat was shown a variety of visual patterns. At first the cell merely exhibited the normal background firing, but when the cat was shown a luminous vertical line, the cell suddenly burst into frenzied life. In the meanwhile other cells in different parts of the visual cortex continued with only background firing. When the vertical bar was slowly rotated so that it was tilted on to the diagonal, the first cell gradually relapsed into background firing but in the meanwhile, another cell began to increase its firing rate. This too "switched off" when the bar was rotated again to a new angle, while yet another cell sprang to life. In this way Hubel and Wiesel, in a memorable series of experiments in the 50s and 60s, began to systematically plot the cat's visual cortex, noting over and over again the fact that individual cells seemed to be specially "labelled" to respond only to specific stimuli. The same applied to cells in the auditory cortex and even—though these were much harder to track down—in other sensory areas. In homely terms what the two Americans had done was to isolate the building blocks of perception, the terminal points in the brain where information being fed in was categorised or classified and where the amazing process of pattern recognition was actually taking place. Similar experiments were soon being performed with a variety of animal species, and also with a range of ages from the infant animal to the totally mature. Here again evidence seemed to imply that with animals higher up the phylogenetic scale, these "perceptual units" tended to be learnt rather than built in, for they were rarely present in the very young animal or the mature animal which had been experimentally deprived of normal environment.

Recent Experiments on the Human Perceptual System.

All this tells one a good deal about the animal brain, but can one make the bald assumption that a recognition system of this kind exists in humans as well? Microelectrode recording with living humans is probably out, except in certain rare surgical cases, so one might expect this to remain an academic question for all time. However, by one of those happy chances which favour scientists from time to time, some recent experiments performed in England suggest that the human perceptual system *does* work along lines similar to that of the animals. These experiments involve a technique which has the rather daunting name of the "stabilised retinal Image," but which is a good deal simpler than it sounds at first.

To see the significance of this one needs first to appreciate the relationship between movements of the eyes and the image projected on to the retina. Looking directly at a pattern of some kind, as we have learnt, leads to an image being focused on the retina at the back of the eye, much as an image is projected on to the film at the back of a camera. Now, suppose that the pattern, instead of remaining stationary, moves across the visual field, then clearly the image moves correspondingly across the retina. Conversely, if the object remains fixed, but one moves one's eyes, then the image is again displaced across the retina. Well, what happens if the object remains absolutely stationary and one keeps one's eyes fixed carefully on it? Does the projected image then lock solidly on to the retina? The answer is actually, no, but for no reason more peculiar than that it happens to be physically impossible to keep one's eyes absolutely still. No matter how hard one tries, the eyes continue to move in a fine, trembling motion, barely detectable without specialised instruments. Inevitably the image of any object in the visual field trembles rapidly on the retina at the same time. This might seem to make vision rather imprecise and blurry, but for reasons we haven't the space to go into, this tremor actually serves to *improve* vision—in particular the kind of super-detailed vision which allows us to see minute specks or very fine lines such as spiders' cobwebs. For some time psychologists have been curious about what would happen to vision if these fine eye movements did not exist, but since they are quite involuntary and automatic the task seemed pretty hopeless. Then someone—the physicist R. W. Ditchburn—had the bright idea of tackling the problem from a different viewpoint. He simply wore a contact lens (which of course acts like a new outer layer to the eye) with a short stalk sticking out of the front of it. On the end of this stalk he fastened a little photograph and a lens to focus the image sharply on the retina. By this trick he had effectively cut out the effect of all movement made by the eye, great or small, because wherever the eye moved now, so the contact lens followed it, and the stalk and photograph followed it too. If you think for a moment you will realise that this means that the projected image of the pattern remains in one position on the retina—the stabilised retinal image. (If you find this difficult to visualise, try sketching the system on a bit of paper—eye, contact lens, stalk, pattern, and of course image on the retina. The logic will immediately be apparent.)

With this system Ditchburn made two very interesting observations. Firstly, the "stabilised" pattern disappeared, thus suggesting that the fine eye movements were essential to visual perception. Secondly, he reported that when a pattern disappeared it frequently did so *in part*, rather than washing out as a whole as one would rather expect. Furthermore, the parts that came and went tended to be neat, even sections of the pattern. For example, a cross would alternate between the vertical and horizontal bars, a triangle would break up into one or other of its three sides, etc. A number of experiments have since been performed with human subjects using this ingenious and unusual apparatus, with results which suggest to psychologists that they are dealing with the same kind of perceptual units Hubel and Wiesel found in the cat. The tendency of the lines to appear and disappear as units when viewed as stabilised images seems to imply that basic "line units" are also present in the human brain—the building blocks of perception again.

It so happens that these fascinating fragmentation effects can be observed by a simple experimental method which does not involve wearing specially fitted contact lenses. You will recall that we spoke earlier of after-images, which are temporary changes in the state of the retina caused by a bright light and these are, of course, perfectly stabilised images since they are part of the retina itself. To observe them oneself the best trick is to sit in a rather dark room and stare at the window-frame against the bright sky outside. Do this, keeping one eye closed and the other as still as you can manage, for about thirty seconds. Then close both eyes and *keep them closed*. After a second or so you will see a vivid after-image of the cross-pieces of the window frame and you will note that the vertical and horizontal bars of which it is composed come and go independently of each other. This is something far more than a trick incidentally—as you do it you will be watching your own brain at work processing the pattern locked on to the retina.

We have spent a good deal of time on vision and visual perception because (*a*) it is easily the most important of the sensory channels, and (*b*) because it is the area of perception best charted by psychologists and physiologists. We will now take a less detailed look at the other senses.

(g) The Ear.

The eyes, as we have learnt, are equipped to detect visual radiations within a fantastically fine range of wavelength—less than a thousandth of a millimetre. From the brain's point of view this takes care of a good slab of some of the most important sources of energy and radiation within the universe, but a brain equipped only with eyes would be "blind" to a good deal of important information. Therefore we find a complete set of specialised receptors handling other areas of interest, of which by far the most important are the ears. These are tuned to pick up waves and vibrations too, but of air waves rather than light, and in an entirely different range. The absolute

spectrum to which the human ear responds is between about 20 and 15,000 Hz (1 Hz = s^{-1}), with a peak sensitivity between about 1,000 and 6,000 Hz. All sounds we can hear, therefore, consist ultimately of vibrations of the air occurring within this frequency range, and in the case of human speech we are dealing with a complex pattern of such vibrations. The ear's method of detecting these and translating them into an electrical code is ingenious and enormously efficient.

Auditory Perception.

The process begins with the outer ears (the flaps of skin on the side of your head!) which serve to catch sound waves coming from the most important direction, which in the case of human beings is in front of them. The importance of these directional indicators is considerable and you can note how strikingly you can change your own auditory perception by flexing the ears with your hand, or cupping your hands so that the "directional indicators" point backwards. Once channelled into the innards of the system, the sound waves are forced down an ever-narrowing tube where they come up against something called the tympanic membrane which is better known as the eardrum. Popular belief seems to be that the auditory process stops here, but from what you have learnt already you can work out that there will need to be much more than this. The translation of the physical vibration of the eardrum into electrical signals will have to take place. In fact the vibrating drum itself sets into motion a beautiful percussive machine in miniature, three tiny and elegant bones known as the hammer, anvil, and stirrup, which carry the message deeper into the ear where they come up against yet another "drum." This is the gateway to a spiral tube called the cochlea, which is filled with a densely packed fluid, and the walls of which are lined with hundreds of thousands of tiny hairs. As the last of the bones in the tiny percussive link beats up against the fluid inside the cochlea, it sets up a series of rapid shock waves which in turn induce complex patterns and rhythms of movement in the hairs linking the cochlear wall—rather like the shifting waves of motion that the sea induces in forests of seaweeds, only on a faster time-scale. These hairs are themselves hooked up to auditory nerve cells and in some way, at present uncertain to psychologists and physiologists, specific movements of the hairs tend to activate specific cells, the end product being that a series of complex but significantly different patterns of electrical activity make their way up the brain. Here the auditory centres get down to the business of interpreting these electrical signals into "meaningful" sounds.

Thinking of the immense sensitivity of the hairs in the cochlear fluid, it may have occurred to you that it ought to be possible to set them in motion by almost any kind of external vibration—and thus hear without vibrating air waves having moved into the ear. This is quite true. Sound waves can be transmitted through other media than air, including bone, and thus even if the ears are blocked one can hear certain sounds remarkably well. Try it for yourself and you will note that the quality of your hearing changes markedly —your own voice, for example, will sound deeper and barely less loud, yet if you whisper you will not hear yourself at all. The reason for this is that with ears blocked, the sound is being propagated to the cochlea by bone conduction and this acts as a filter, cutting out the high-frequency components almost totally but letting in the lower notes without too much trouble. This is why earplugs are disappointingly ineffective.

This is probably enough about the ear which, if the truth is known, is rather less well understood by psychologists than the eye. Only one major point might be briefly touched on. Why do we have two ears rather than, say, one large one on the top of our head? The answer is that a binaural system allows us to locate sounds rather better; slight differences in the time it takes for sounds to reach each ear (as when one ear is slightly closer to a sound source) cause fractional delays in the arrival of the respective signals to the brain—enough for the magnificent computer there to deduce the sound source's rough location.

(h) Smell, Taste, and Touch.

Olfaction.

Of the remaining three senses, only one is concerned with detecting objects at a distance after the fashion of vision and audition. This is olfaction or, as we generally call it, the sense of smell. Olfaction is particularly interesting because it is concerned with the detection of chemical substances in the air, rather than with wave or vibration analysis. Animals of all kinds make much use of their ability to recognise the chemical changes taking place in plants, other animals, etc., which serve to indicate "good" (*i.e.* necessary for survival) or "bad" (*i.e.* dangerous) objects. These may range from the sweet smell of edible fruit, the characteristic odour of a mate in a sexually receptive state, or the nauseous smell of rotting flesh, riddled with dangerous bacteria. Unlike vision and audition, the olfactory sense mechanism is relatively simple in form, consisting of two small patches of cells situated rather high up in the nasal passages and not in the main line of breathing. This accounts for the animal habit of sniffing to detect smells better, the sniff being a method of pushing air up into the rather inaccessible smell receptors. As with pretty well everything else in the body the olfactory receptors are specialised nerve cells, immune of course to light or air vibration, but incredibly quick to react to a wide range of airborne molecules. The presence of particular molecules on a receptor causes a chemical change to take place in the cell, this in turn inducing an electrical signal to pass up the olfactory nerve. Psychologists have not spent too much time on this sense for it seems to be of relatively low importance to modern man, but have pondered the interesting question as to just how many different kinds of smells human beings can detect. You might try to think about this for yourself and before you say hundreds, you should realise that most smells, like most colours, are probably mixtures of a relatively small number of primaries. There is, as it happens, no definite agreement as there is on the seven colours of the visual spectrum, but an early classification by the psychologist Findley in 1924 has probably not been bettered. His "smell prism" listed six primaries which you may like to compare with your own choice. Each smell is identified with a substance which Findley thought was a typical generator of the odour. (1) fragrant (oil of jasmine), (2) etherial (oil of lemon), (3) resinous (turpentine), (4) spicy (cinnamon), (5) putrid (hydrogen sulphide or rotten eggs) and (6) burned (oil of tar).

Taste.

We now move from the distance senses to the so-called "proprioceptors" which is the name psychologists give to the senses concerned with the detection of things actually in contact with the body. Although it is not classed in this way the logical one to look at next is taste, which has much more in common with smell than most people imagine. Taste in itself is a rather feeble sense, mediated by a number of chemically sensitive receptors on the back and sides of the tongue, and the relative overemphasis of its importance is due to the fact that when people talk about great subtleties of taste they are generally talking about great subtleties of smell, for the latter is vital in any gastronomic treat. The simplest test of this is to sample some particularly good tasting substance, savour its flavour and then hold one's nose. The reduction in taste is dramatic, and one can soon realise how a bad head cold can have such drastic effects on the enjoyment of food and drink. One other remarkable feature of the sense of taste is how quickly it adapts out—a drink which tastes sweet or sour at the first taste, slips into bland neutrality before the glass is emptied. This is another experiment the reader can surprise himself with, particularly if he holds his nose while drinking, thus elliminating the vital smell component. The classification of tastes is somewhat easier it seems than that of

smell, with most psychologists settling for four primaries, with which you will probably find yourself agreeing—sour, salt, sweet, and bitter. Anyway the plain fact is that the gustatory sense is a very limited tool in mankind's sensory workshop and poses few experimental questions.

Touch and Sensitivity to Pain.

The remaining sense, that of touch, includes under its heading a good deal of sub-senses such as the detection of pressure, heat, cold, and the highly enigmatic pain. Pressure, heat, and cold are fairly well-understood, probably being mediated by a number of different types of specialised cells embedded in the skin. Much controversy surrounds the number of different types of receptors involved and the matter is complicated by the fact that no one has positively identified a "pain" receptor—*i.e.* one which fires only when a potentially dangerous stimulus contacts the body. An early view held that pain was simply the signal the brain received when any kind of stimulus was excessive, but for a number of reasons this will not do. There are also some peculiar factors such as the observation that it is not all that easy for a person, without any other cues, to tell the difference between hot and cold objects. Immersing a finger in icy cold water and in very hot water briefly provokes a generally unpleasant sensation, but it is hard to tell with the eyes closed and without prior knowledge which end of the temperature spectrum is being experienced. Pain itself, the scourge of mankind (and yet his saviour in cases where it keeps him out of danger) is an incredibly mysterious phenomenon and we will not be able to say much about it here except to point out that much of its operation is determined by processes going on in the brain rather than in peripheral parts of the body. Human sensitivity to pain also varies enormously. Among certain rather neurotic people intense pain may be felt at relatively minor physical afflictions, while other people may bear (or learn to bear?) what would generally be accounted as gross physical discomfort with equanimity. The action of pain-killing or analgesic drugs is also very poorly understood. Some recent exciting studies by the physiologist, P. D. Wall, suggest however that we may be on the edge of a major advance in our understanding of pain. He has shown that in certain cases of otherwise intractable pain —following, say, serious limb injury—great relief can be achieved by the electrical stimulation of certain "inhibiting nerves" *in the site of the wound itself*. This is not counter irritation but somehow bringing into action a "damping" or inhibiting system which in the area of the wound had ceased to function properly. In extraordinary experiments patients have been taught literally to switch off their pain by stimulating these inhibitory nerves with a small electrical device at the side of their bed. Other experiments along these lines are presently taking place in various parts of the world, and brain scientists are watching their outcome with the greatest interest.

(i) Are there any Other Senses?

If we take pleasure and pain as separate senses, which might seem reasonable, then even forgetting about all other possible sub-divisions of sensory detection the traditional five senses are not enough. Most psychologists, however, are content with the traditional categorisation. One important area not particularly well covered by the present human sensory range is that of high energy radiation beyond the ultra-violet. It so happens that until quite recently few living things came much into contact with radiation of this kind—the odd cosmic particles bursting through the earth's envelope of air, while dangerous, are too rare to be worth developing special receptors for. Within the past century, however, man has begun to work regularly with high-energy radiation sources and has suffered a good deal as a consequence. X-rays, for example, were grossly misused in the early days after their discovery, and similarly numerous deaths have been caused by the misapplication of nuclear fission devices. The problem is simply that although the radiation is doing our body mortal harm, we expose ourselves to it because we are not equipped with "radiation detectors" to warn us. Once the pain arising from tissue damage arrives—it may take decades for the damage to become apparent—it is too late to do anything about the original stimulus. This apparent digression is merely to remind one of the tremendous role the senses play in our lives, and how brief our span of life in this dangerous universe would be without them. But what of other senses? A frequently used term is that of the "sixth sense" and many people believe that humans and animals are equipped with some other major sense which allows the creature either to detect some danger at a vast distance—way beyond the range of vision or audition—or alternatively to allow one mind to communicate with another mind. We discuss this problem briefly in the section on Ideas and Beliefs, but it also has a place here since many people believe that the study of extra-sensory perception is a legitimate branch of modern psychology. The first argument against the idea of ESP (you may not feel it is particularly convincing) is that no one has been able to detect any mechanism in any part of the brain which could possibly be transmitting or receiving the messages conveyed by the sixth sense. Believers in ESP reply (*a*) that one might be discovered at any time, and (*b*) that perhaps no transmitter or receiver is necessary anyhow. The first point is of course irrefutable, but the second raises a different question and suggests that whatever mind-to-mind contact is, it cannot be looked on in the way we have been attempting to look at either sensation or its necessary complement, perception. There is an even more cogent argument, however, which the vast majority of psychologists today adopt—that there is simply no experimental evidence for the existence of telepathy anyhow. In this case it is quite unnecessary to start looking for mechanisms to mediate it. In experiments conducted to sort out the ESP controversy, psychologists *have* found that people are very much better at gathering information from each other without the use of speech than had hitherto been realised. Tiny changes in facial expression, nervous movements, shifts of eyes, even long periods of unusual silence can all serve to give the trained observer important clues as to what is going on in another person's head. Fortune tellers, detectives, and expert card players have known this for years and are only too aware that they are getting their information by clever and insightful use of their normal senses, but rely on other people's ignorance of just how good these mechanisms really are.

(j) Sensory Deprivation.

Any individual, human or animal, born without a reasonably complete complement of senses would almost certainly be doomed to an early death or a life of relying on other humans for assistance. A few startling souls, such as the late Helen Keller, fought their way out of the solitude of total blindness and deafness to lead full and useful lives, but these are golden exceptions to a fairly inflexible rule. Miss Keller in her autobiography tells of her gradually emerging realisation that the universe consisted of "other things" outside herself and states that it was only through an understanding of this that she began to form the concept of herself as an individual personality. This serves to reinforce the point of view stressed by modern psychology that the individual is a mesh between himself and his environment. True personality has no reality without constant and evolving interplay with the external world. But what would be the effect on the normal personality of inducing enforced perceptual isolation?

In the early 1950s, as scientists began to see that man would soon be able to make voyages into space, the psychologists began to ponder how well human beings could stand up to the physical and psychological isolation of a space capsule. Man is gregarious, naturally at ease among his fellows, and tends to become eccentric and unbalanced when separated from other humans for any length of time. What, they asked, would be the effect of the extended and rather dramatic isolation imposed on the astronauts of the future? To test this a number of experiments were set up

in which people were isolated in sealed chambers under conditions of greatly reduced sensory input for lengthy periods. Initial studies seemed to show that the experience was unexpectedly unpleasant, and, sensing that they were on to something significant, psychologists at McGill University in Montreal, where the pioneering work was done, decided to tighten up their experimental situation. Students were hired at the relatively princely sum (for students) of a dollar an hour and told that they could spend as many hours in isolation as they pleased. They were then placed in stuffed clothing rather like divers' suits, and lowered into chambers of water maintained at body temperature. The helmets of their suits were lightproof and the chamber was sealed and covered to be soundproof. The outcome of all this was that even if the student made a body movement he would feel no apparent response as his body, encased in the bulky clothing, would merely float around in the unresisting water. External vision and sound being eliminated, and with ears plugged to prevent him hearing his own breathing, the subject was in a state of almost total sensory deprivation. His only link with the outside world was a "panic button," which he could press to alert the experimenters if for some reason he wanted to terminate the experiment. What did the psychologists expect? That most students would like nothing better than to do nothing for weeks on end and get paid a solid wage for doing so? The results surprised everyone. Most subjects had had more than enough after only a few hours, and only one stuck it out for more than a day and he suffered a neurotic hangover for his pains. For human beings, total isolation from sensory input is evidently one of the most unpleasant experiences imaginable.

The experiments caused a surge of controversy and a good deal of speculation as to what the results implied. The students' principal objection was that they became oppressed with vivid and bizarre hallucinations, both visual and auditory, apparently comparable in strength and unpleasantness to the hallucinations reported by alcoholics suffering from *delirium tremens* or (more fashionable today) the worst excesses of an LSD trip. These vanished as soon as the subject was removed from the chamber and apparently did not occur again. The first hypothesis advanced was interesting—that living things have a hunger or need for sensory input, comparable, but of greater strength, to the need for food. Furthermore, when the sensory appetite was not assuaged, the brain began in desperation to create its own sensory material, hence the hallucinations. This hypothesis was unchallenged at first, but an alternative point of view has recently been put forward based on the recent discoveries in the field of sleep and dream research. Many psychologists now believe that humans need to dream and that one of the principal functions of sleep is to allow our brains to undergo a kind of sort-out of the programmes which control the central computer. In this view the hallucinations occurring during sensory deprivation would really be an example of the individual dreaming *while he was awake*, the subject's brain having been fooled into "thinking" that it was asleep by the sharp reduction in sensory input which had occurred. For various reasons the human brain carefully keeps the important process of dreaming separate from the waking state and there is some suggestion that to fully experience our dreams would be a psychologically intolerable experience. If this is correct then the McGill experiments and their successors show not a need for sensory input with consequent hallucinations to feed the sensory appetite, but rather the effects of allowing waking human beings a glimpse of the "inner space" of their minds. Similarly, incidentally, one can look upon both the LSD trip and the alcoholic hallucinations as examples of the same process occurring—except that the tripper has stimulated his dreaming mechanism into action through the drug, while in the case of the alcoholic, his excessive intake of alcohol has led to an inhibition of the normal dream process which bursts into activity when he is awake. Whatever the explanation for the strange experiences of the isolated students, there is no doubt that the human being is not psychologically equipped to face up to total loss of sensory inflow for any sustained period. The adventures of the astronaut have in fact taken place in relatively richly-endowed sensory environments and so the expected problems have not arisen. But what of space voyages lasting for months, or even years?

(k) The Problem of Attention.

We have now really finished with the senses and perception as such, but before moving on to our section on Learning and Information storage, we need to think a little bit about the problems which are posed by the great influx of information to the brain, how it sets about coping with this and how it assigns priorities to the multitude of signals it is faced with. This involves the process which we know as Attention. To get some idea of the task facing the brain, let us take up another simple analogy, even if it isn't 100 per cent accurate to the purist's eye.

The brain can be likened to a complex communications centre, sorting vital information, rather like an air traffic control at an international airport. Information floods in from various sources, with the controller paying attention to the scene through the windows, to radio calls, to messages coming by teleprinter and by hand, etc. One way to sort out the muddle might be to assign one mode of messages to one controller, the second to another, etc., but the problem of co-ordination remains. At some stage the senior controller must select which set of signals he is to work on, switching when appropriate to other sets, and issuing instructions to the aircraft waiting to take off and land. Now there are two ways in which he might select the information. The first would be to cut off the unwanted signals at his desk by refusing to allow the stimuli to reach him, a strategy which might lead to a jam of information such as messengers, bits of paper, telephones off the hook, etc., cluttering up the control room. A second strategy would be to staunch the flow of information in the unwanted channels closer to their source, in this case at the point where they first come into the control tower. Real air traffic centres, fortunately, never get into the kind of muddle we are implying here, and nor, in most cases, does the brain. But which of the above strategies is the closest to that adopted by the brain in attending to one particular set out of a vast pool of competitive information? Until about 10 years ago psychologists tended to favour the idea that the first of the two systems was in operation with every sensory stimulus making its way to the brain to contribute to some great tangle in need of constant sorting out. Confusion and uncertainty under stress were considered to be an example of the tangle getting momentarily too complicated.

This view has now been largely rejected thanks to some brilliant experiments by the outstanding young Mexican psychologist, Raul Hernandez-Peon, who was recently tragically killed in a car crash. Hernandez-Peon's experiment, which many people consider to be the first big breakthrough in the psychological study of attention, was performed first on that most useful of laboratory animals, the cat, but later repeated on other creatures. The first stage was to implant a microelectrode into the cat's brain, specifically in an area known as the cochlear nucleus. You will recall the word cochlea from our section on audition, as being the seat of the translation of the incoming sound waves into electrical signals. Now the cochlear nucleus is the first major junction box at which auditory signals meet before beginning their ascent to the brain. Prior to this there is only the network of neurones springing directly from the tiny hairs in the cochlea itself. By attaching the electrode to an amplifier and looking at the output on a TV screen, the experimenter could watch the electrical impulses from the ear as they passed through the big nucleus. The ticking of a metronome, for example, could be seen as a regular beat in time with the tick. Hernandez-Peon then set about trying to attract the cat's attention away from the metronome and did so by showing it a mouse. The cat, as predicted, gazed interestingly at the mouse whereupon—the electrical signal indicating the still-ticking metronome vanished from the TV screen! This is odder than one thinks at first. Remember

that the electrode was planted in the nucleus in the region of the ear, and yet the electrical signals were no longer passing this point. If the metronome was still ticking, then its sound waves should still be activating the ear and should still be trying to send their impulses up the auditory nerve. Clearly then, a gate was being closed not in the brain but right down at the level of the ear—the message to close it, however, presumably being sent down from the brain. How could this gate-shutting message get down to the ear? Evidently there must be neural fibres which send their messages downwards from brain to receptor and not just in the other direction as had hitherto been believed. These corticifugal fibres, as they are called, are now believed to run to other sensory areas, including to the retina in animals and humans, and while they are very difficult to track down by anatomical analysis they are thought to serve a very important function. The facts of the case seem to be that Hernandez-Peon had discovered one of the basic mechanisms of attention, the ability of a creature to filter relevant from irrelevant information. Thanks to his work it now looks as though the brain prevents itself from having to face a muddle of conflicting information by cutting off the unwanted signals actually at the level of the receptor, thus preventing a press of confusing and irrelevant information from flooding in. Once attention shifts again, then the appropriate gates are opened and information flows as before. If this tells us something about the selective filtering of important as against useless information, does it also say something about the way a mother will be undisturbed in the night by the flight of a jet plane and yet wake to her child's slightest cry? Perhaps this is an area which mothers know more about than psychologists ever will.

III. LEARNING AND MEMORY.

(a) How is the Information Stored?

Earlier we discussed the specialist use of the word information that psychologists and other scientists employ and remarked how important it is for an understanding of current work on the brain that one rids oneself of the idea that information can only be conveyed in the form of spoken or written messages. We now need to consider the general problem of the *storage* of information, a concept fundamental to the interesting topics of learning and memory. Most people can readily accept the idea that a book is a store of verbal information as, in a different way, is a gramophone record. In reality in neither case are words actually stored. In books the information is held in the form of coded marks, called printing which need to be decoded by the reader before he can understand the original message. Similarly in the case of the gramophone record the information, which might be the sound of a pop star singing, is coded into the form of a series of ridges on a plastic, the decoding being done by a needle plus amplifying equipment, speakers, etc. Using devices like books, films, and records, information can be held in store for very considerable periods of time, the original message sitting around more or less indefinitely until someone gets down to decoding it. Messages written on the walls of prehistoric caves by our dim and distant ancestors are still passing their information across today, and even the fossils we find in Cambrian rock formations are messages of a kind, though the senders did not consciously originate the signals. In essence then a message consists of an information source, some kind of transmitting medium and a receiver. There may also be a delay built in—storage—in which case some kind of encoding and decoding process will be added to get the message in and out of store. All this preamble leads us now to the point where, having in the previous section considered the information gathering and decoding processes in the brain, we can now consider its role as a storage device. Unlike books and records, which operate on fairly simple lines, the brain chooses immensely complicated and still rather mysterious techniques to do its job.

First, perhaps we should clear up a small point which otherwise will cause confusion—the fact that psychologists distinguish clearly between the two processes, learning and memory. In fact the distinction is simple, particularly in the light of the principles we have just been considering. Learning is the process of feeding information into store, and memory (or remembering) the process of extracting it once again. The next question is the really big one—in the case of the brain just how is this done?

Returning momentarily to gramophone records and books we can see that the process of information storage implies that the incoming signal has changed the state of the storage device, book, record, or whatever, in some way, either by covering it with marks, ridges, or, in the case of magnetic tape, altering the electrical properties of its surface. Something similar must happen in the brain. Information flows up from the receptors, is processed or interpreted by the perceptual mechanism, and then, depending upon circumstances, fed into some store where it is held until required. What kind of changes could be taking place in the neural circuitry of the brain to constitute the laying down of a memory? Psychologists have been divided on this question for decades, and there are three fairly separate competitive approaches. Without giving too much away we shall probably end up feeling that the true explanation will turn out to be some kind of mixture of all three. The three main suggestions can be summarised as (1) the neurological, (2) the biochemical, and (3) the electrical.

The first suggests that as information is fed in, causing certain patterns of brains cells to be activated, minor changes take place on the structure of these cells, modifying them in a rather gross, physical way. This would be similar in a sense to the changes that take place in the surface of a gramophone record when it is first made. The second argues that such gross changes are unlikely and that the storage must take the form of modification of the biochemical or even molecular structure of the brain, changes taking place *within* rather than on the surface of individual cells. The third view advances the hypothesis that since the brain is a mass of electrical energy, and electricity is the basis of neural activity, then the psychologist should look for changes in the electrical patterns of the brain as an index of the fact that something has been stored. We will look at each point of view in greater detail shortly, but first it will be useful to study the experimental evidence.

(b) Early Studies of Learning.

Experimental psychology started in the latter part of the 19th cent. largely as the result of pioneering work of the German physiologist and psychologist Wilhelm Wundt. No one today gets greatly excited at Wundt's experiments nor at his writings, but he was one of the first people in the world to realise that one could actually subject the raw material of mental activity to the experimental method and in this way he is memorable. Wundt concentrated on perception and similar topics and also conducted the first studies of reaction time—the delays humans make between being given the signal to start a task and actually beginning it. He had little to say about the matter of learning and memory, leaving it to a successor, Hermann Ebbinghaus, to get the ball rolling in this area.

Ebbinghaus's experiments were beautifully simple. He took human beings into his laboratory and set out to teach them lists of words, plotting the success rate (number of words in a sequence remembered) against the number of repetitions that had been given. This may all seem frightfully obvious, particularly when we say that Ebbinghaus found that the more repetitions, the better the list of words were learned. This is exactly what one would expect now, a century later, but at that time things weren't so clear cut. Furthermore, Ebbinghaus showed that when you plotted the rate of learning on a graph, a very characteristic curve emerged, common to all his normal subjects, which indicated a gentle improvement in learning with the first few repetitions of the list, followed in due course by a sharply accelerating rise which in turn tapered off. Finally a point came when the list was either

completely learned, or no further improvement was made. The important factor was that while there were individual differences in the final level of achievement, and also in the time taken before the main surge of learning took place, the shape of the curve was very similar for all subjects. In other words, while there were significant differences in the ability of subjects to learn his word lists, the nature of the learning process seemed to be interestingly similar. Ebbinghaus's findings are as valid today as they were then and his learning curve fits rather well to the overall pattern of animal learning as well.

In his quest for objectivity he produced another interesting idea. It seemed to him that if one were to compare the performance of two different people in a learning task, one couldn't deduce much about their respective talents by examining the slope of the learning curve unless one knew something about their previous experience with the subject matter. For example, one person might, because of his job or something, simply have been more frequently exposed to the material featured and this would give him a built-in advantage which confused the issue. How about using foreign languages? Again Ebbinghaus felt that to get absolutely pure learning curves one would have to be certain that the subjects had not received prior exposure to the languages in question, a task almost impossible in principle. This led to his invention of a curious tool in the psychologist's workbox, the nonsense syllable, which is still used today as the standard material for many tests of learning ability. It consists of a word with a meaningful sound and look to it, but which is almost complete nonsense inasmuch as it has no obvious meaningful association. ZAT, BOK, FID, BIJ, HAB are a few examples of this strange vocabulary. Ebbinghaus-type experiments are, as you can believe, immensely boring to perform and subjects today normally have to be paid in order to persuade them to take part! However, his realisation that human learning processes could be brought into a real, if rather dull, laboratory setting was a big step forward. Furthermore he had realised the necessity of separating out performance in one task from the background of past experience, an idea which has had far-reaching consequences on the design of all psychological experiments since and which even touches on the important question of the interplay between heredity and environment which we shall look at in the final section.

(c) Learning Experiments with Animals.

The use of nonsense syllables gets over the problem of past experience in one limited area of experimental psychology only, and if one really wants to know something about the formation of the learning process from scratch then one either has to start with very young babies, or use laboratory animals. One psychologist went so far as to read aloud lengthy passages of Greek prose to his infant son at an age when the baby couldn't even understand English. Years later the psychologist gave his son, by now a young man, a number of passages of Greek prose to learn, among which were the sections the baby had previously heard. The outcome was that the sections to which the child had been exposed as a baby were found to be significantly easier than the fresh material. This odd and very tedious experiment has never been repeated, though it is generally rejected by psychologists today as having been imperfectly controlled. For example, who can say for certain what the young man had or had not learnt in the period between the two phases of the experiment? It nevertheless remains as one of a few heroic efforts to use young babies as subjects in learning experiments and it also highlights some of the great difficulties involved.

By the turn of the century more and more psychologists were beginning to follow the lead given by their physiological cousins in bringing animals into the research laboratory. One of the first and most important figures to do so was the American Edward Thorndike, who began to look at the behaviour of specially bred white rats in laboratory learning experiments. Now with humans the problem of how to get the subject to do what one wants him to—learn nonsense syllables or whatever—is met by simply speaking to him about it. With animals this won't work, so Thorndike decided that they would have to be rewarded in some way if they were to learn anything. Reward can be any one of a lot of things, and for an animal it can be getting out of a situation it doesn't like, such as some kind of maze or puzzle box in which a number of specific moves have to be made in sequence before it can get out. Thorndike found that most animals make strenuous and fairly determined efforts to get out of boxes, mazes, etc., and can follow a fairly elaborate sequence of moves in order to reach their goal. Rats, for example, will learn to press a series of levers in the right order if they will open the door to a box, and they will gradually get better and better with practice. Similarly, when placed in a complicated maze, provided they are rewarded with food or escape at the end, they will soon find their way round it. The crucial point here seemed to be the reward, and while pet owners have known for centuries that a piece of sugar presented at the proper time will make a pet do tricks, it is really not clear why it should. To say that it is because the animal "wants the sugar" is no explanation as to why this trick should be learnt rather than some other pattern of behaviour. But Thorndike found without doubt that an animal would learn a maze or similar task far better if it were rewarded in some way at the completion of the task, and he too couldn't see just why, in physiological terms, the neural events which made up the correct performance of the task should be "built in" simply because the animal was rewarded, while incorrect patterns of behaviour were rejected. Ebbinghaus had come to the conclusion that successful learning was a function of the number of times the task was repeated. Thorndike argued that while practice helped to make perfect, it needed something else as well—*i.e.* the successful completion of the act. How would one measure success? Well, getting out of a maze or finding sugar at the other end would presumably count, and Thorndike described this principle as the "Law of Effect," believing that he had discovered two factors necessary for learning to be successful (for the information to be placed into the store), one being *frequency*, the other being *effect*. Psychologists at the time carefully sidestepped the niggling question of how *effect* (something happening at the end of a sequence) could work back in time to establish the sequence in memory by arguing that the reward or reinforcement did not itself cause the sequence to be stored in the memory system. It simply made that sequence more likely to be called up on some future occasion. But, replied the critics, wouldn't that imply that all sequences were stored with both right and wrong behaviour lodged equally firmly in memory? This question is still being hotly debated today, and we will shortly be taking a look at the evidence concerning what is and isn't learnt in an experimental situation. But first a word about one of the most important concepts not only in modern psychology, but also in 20th cent. science—the conditioned reflex.

(d) Pavlov and the Conditioned Reflex.

The great Russian physiologist Pavlov reached the peak of his scientific genius in the early years following the Communist revolution in Russia, where his very physical approach to psychological phenomena found favour with his country's leaders. The reasons were ideological. To many it seemed that Pavlov could explain all behaviour in purely mechanistic terms and thus do away with mystical, metaphysical, and, to Communist thinking, totally out-of-date views of Man's nature. Pavlov, it was felt, was at last exorcising the Ghost out of the Machine. His findings in fact sent ripples across the world, and the face of psychology was changed by them—notably in injecting into it the realisation that a good psychologist must think like a physiologist at least as often as he thinks like a philosopher. On the other hand, his naively simple view of the machinery of mind and brain was bound sooner or later to be exposed as only partially adequate.

missing many of the richly complicated facets of human behaviour which must be faced up to and not denied. What was Pavlov really saying? At rock bottom his ideas revolved around the notion of the conditioned reflex arc, a concept that all wishing to understand modern psychology must get clear in their minds sooner or later.

The experiments in question were exceedingly simple inasmuch as they confined an animal to a rather limited environment and studied its behaviour in the most fundamental kind of learning situation. Pavlov, who was enormously interested in gastric and salivary secretion, had noticed that some of the animals in his laboratory would respond to the presence of food with copious flows of saliva, while others would not. Some would even respond excitedly when a particular food pan appeared while others again would not. He reasoned that these differences were in some way a function of the particular animal's past experience and set out to study this in detail. Firstly, he devised a method of measuring saliva flow, which would normally be copious when an animal was presented with its food bowl. He then introduced, just prior to the presentation of the food, a buzzer, bell, light, or some other similar stimulus. Initially the preliminary stimulus would yield no salivary response, but after a while, provided that the pairing of the presentations was kept up, the first traces of saliva would begin to appear upon the sound of the bell. If this were reliably followed by food, soon the saliva would appear in full flood to bell alone. Failure to offer up the food, however, if persistent, would lead to a gradual falling off in the amount of saliva until it ultimately dwindled away. Pavlov declared that this must imply that a probably instinctive reflex—salivating to food—had become linked in neural terms with a stimulus which had at first been totally irrelevant, the sounding of a bell. The more frequently the two events were linked and the more closely they were associated in time, the stronger the new reflex arc would be. Lack of association between bell and food would lead to the extinction of the reflex arc. The fact that extinction was not total could be nicely shown by introducing the food again, whereupon things would come rapidly back to normal with the bell producing copious flows of saliva once more. Today this seems a fairly trivial observation, but at the time Pavlov, his co-workers, and psychologists all over the world became immensely excited about the conditioned reflex. The reason was that there seemed to be no reason in principle why the whole of an animal's behavioural responses had not been acquired in just this simple way with the same argument applying with equal force to humans. At the root of all behaviour lay a simple physiological principle. By employing this properly, all living things could have their behaviour patterns moulded in whatever direction was felt to be appropriate, all psychological malfunctions could be corrected, education made simple, the wild beast tamed, the workings of the brain fully described and comprehended. This, for a brief period, was the golden goal (if one likes to think of it in that way) of the new science of psychology—to see man for what he really was: a complex mass of inherited and conditioned reflex arcs.

If Pavlov and his followers in Russia clung to this dream for decades longer than did less politically committed scientists in other parts of the world, then this is understandable. One of the goals of scientific endeavour is simplification and an explanation of human behaviour in terms of stimulus–response units would certainly meet part of that goal. But on the other hand part of the goal of science is also objectivity—even at the risk of complicating explanations—and before long it became obvious that the animal in the experimental Pavlovian set up was *not* behaving as a complicated automaton. For example, it is possible to condition an animal to lift its foot to avoid an electric shock if a bell reliably signals the imminence of the shock. Now place the animal on its side, ring the bell and—will the animal lift its foot? Yes—but not before getting up to the standing position first. But if the animal is blindly responding to the firing of a neuro-muscular reflex arc, why does it not simply raise its foot while lying down? And how does the standing up act become incorporated into the reflex sequence without prior training? Such experiments were simply discounted at first as being too inconvenient for the theory, but as time went on the immense oversimplification of the stimulus – response theory of behaviour became obvious. But not before a major movement sprang up in the United States which attempted to make dynamic and imaginative use of Pavlov's findings in an attempt at an all-embracing psychological theory. We now turn to look at this, the so-called Behaviourist School.

(e) The Rise of Behaviourism.

Sometime before Pavlov's ideas began to have impact in the West, a spontaneous movement had been developing among psychologists to reject the traditional methods of introspection in experimental research. The interplay of conscious thought and mental activity was felt inevitably to confuse the issue, and workers were urged wherever possible to make objective rather than subjective judgments. One of the hardest advocates of this line was J. B. Watson, who even went so far as to argue that introspective studies of consciousness, etc., were not merely misleading, but positively useless. In principle, Watson proposed, it should be possible to give a total explanation of the subject matter of psychology—whether human or animal—in descriptive, mechanical terms concerning the outward manifestations of behaviour. This implied ultimately taking such extreme points of view as declaring thinking to be merely "sub-verbal speaking," better described in terms of minor twitches of the throat, mouth, and tongue muscles than in patterns of electrical activity in the higher centres of the brain. All that was needed to give the Behaviourist school impetus was Pavlov's discovery of the conditioned reflex, and when this was published it was eagerly incorporated as the prop of Watson's argument. To Watson and his colleagues the only realistic and profitable way to look at human and animal behaviour was in terms of a strictly mechanistic model, the conditioned reflex arcs serving as the vital links in the creature's chain of activity. Now many people might agree that an animal in a highly restricted laboratory situation, trained to salivate to bells, raise its paw to avoid an electric shock, etc., might well be coming as close to a biological machine as one could imagine, but was this a really adequate way of describing its behaviour "in the wild"? Critics of Behaviourism were quick to point out certain peculiarities that they felt could not be handled by Watson's simple system. Take a dog, for example, and face it with a series of doors, behind one of which is to be found food, sometimes one door, sometimes another. Now train the dog to respond to a light switched on briefly as signalling food. Now indicate the door which has food by switching on a light above it, and the dog will soon learn to trot up reliably to the appropriate door. What has happened? Easy say the Behaviourists—the dog has been conditioned to approach a light for food, and the reflex carries over to a light above a door. The dog is not really responding to the door, but to the light which sets the appropriate reflex arc in motion, just as pushing a button can cause a car to start. But what, the critics argued, about the fact that the light is switched on for only a few seconds, and yet even after it is off the dog still moves towards the door? Watson replied that the light caused the animal to look towards the door and it immediately adopted a particular posture, setting its musculature up so that it would set off in the appropriate direction, no longer needing the light for a guide. This might seem fair enough, but for the fact that if, just as the animal is about to set off for the door, you hold it, refusing to allow it to move, it still "shows interest" in the door. Furthermore, if you let go in five minutes time, the chances are that the animal will set off to the correct door—a bit long one would have thought for the reflex arc to have been maintained in suspended animation. Was it not simpler, Watson's critics replied, to face up to the fact that the animal was using the light as a signal and was holding the door in some mental form as a kind of goal to which it could make a delayed response if necessary? So adamant were the Behaviourists that all behaviour

could be explained in terms of sequences of conditioned muscular movements that they strove to argue that even during the delay the animal was still maintaining a muscular posture—rather in the way that a hunting dog freezes to point to prey. Furthermore, Watson produced what he believed to be irrefutable evidence for the dominance of the muscular activity, even on a task as complex as learning to run a maze. In this rather cruel-sounding experiment he trained a whole lot of rats to find their way through a rather detailed maze. He then preceded to eliminate by surgery all normal sensory equipment—eyes, ears, smell, etc., leaving only the kinaesthetic, or touch, sense. These grossly deprived animals nevertheless still managed to find their way through the maze, allowing him to conclude that in line with the conditioned-reflex notion, the animals were relying predominantly on a chain of muscle reflexes. For a brief period this dramatic experiment seemed to clinch the Behaviourist case. But then came a counter-experiment, even more drastic. A psychologist called Lashley repeated Watson's experiment, but this time also removed the sense of touch by spinal surgery. The wretched creatures even now managed to stagger through the maze—though they were certainly no longer equipped with proper muscular responses. Lashley, correctly, felt this dealt with the ultra-simple Behaviourist argument and that somehow or other the animals must be retaining some kind of general directional sense, a sort of "notion" as to where the exit lay. At about this time more attacks on Behaviourism came from a rival point of view—the Gestalt school. Watson himself shortly afterwards became involved in a sensational divorce case which forced him, in those less permissive times, to resign from academic life. He ended his brilliant career in, of all things, the advertising profession.

(f) Gestalt Psychologists and Learning.

With its emphasis on such ideas as "the whole is something more than the sum of its parts" and its insistence on the idea that the brain has dynamic organising powers which serve to modify input and intervene between stimulus and response, the Gestalt point of view was clearly about as far removed from the naive Behaviourist viewpoint as was possible. One of the principal allies of the Gestaltists in its early days was K. S. Lashley, referred to above, a brilliant experimentalist with an eye for the essentials of the problem. Throughout his long research life he remained open-minded about various schools of psychology and unconvinced on the various rival theories concerning the physiological basis of memory. He was, however, quick to see the basic weaknesses in the various brain models that fellow psychologists were always confidently erecting, and the first to feel the sharpness of his attack were the Behaviourists. Lashley swiftly realised that the attractive simplicity of the Pavlov/Watson argument was that the basic unit in learning consisted of a fundamentally simple physiological system, a neural reflex arc. In ordinary terms this could be looked on as a chain of cells connecting from, say, the retina through the higher centres of the brain (where the chain would be forged) down to the muscle or set of muscles which constituted motor output. In other words, a light would strike the retina, a number of cells would fire. These in turn would excite cortical cells which had, by prior conditioning, become linked into a reflex arc. Finally these would, quite mechanically, induce the appropriate muscular response. The memory itself constituted the connecting cells in the cortex, and this memory had been established by the learning or conditioning process. Lashley then realised that a memory unit, or an engram as he named it, must be represented by a particular set of cells in a particular part of the brain. In principle, therefore, one should be able to discover these sets of cells and find out what kind of memory is located in what part of the brain.

Lashley's technique was again that of surgical destruction of tissue and using this he performed one of the most remarkable experiments in the history of modern psychology and physiology. His findings created a shock of disbelief and controversy, and their full implications are still not fully understood today—about 50 years after he performed the experiment. Taking a large number of rats, he trained them until they were highly familiar with a complicated maze. He then proceeded to remove from each rat a small portion of cortical tissue, taking a different area but an equivalent amount from each rat. In due course he had removed from his collection of rats the equivalent of one complete brain, though no individual animal had had more than 5 per cent of its cortical tissue destroyed. He then took another set of rats, trained them in the maze, and again removed the equivalent of a brain, but this time taking 10 per cent from each rat. With a further sample he went through the procedure again, but removed a quarter of each rat's brain, and in his final group he had a limited number of animals, each of which had had half its cortex removed. See if you can work out what he found. Remember that if the memory or engram consisted of a series of linked cells then one might expect that these would be found in one relatively small segment of the brain. Interrupting the chain at any point should presumably destroy or grossly handicap memory. Now from the simple behaviourist point of view, most people would have to predict that one or two rats whose hunk of cortex removed had featured the conditioned reflexes involving the maze, would be completely clueless when placed in it. The engram would have been removed. This would then tell the experimenter, as Lashley had hoped, which part of the brain dealt with such tasks as maze learning. Other animals, who had not lost their maze engram would show no detriment in their performance of this task. To his amazement, and to everyone else's for that matter, Lashley found that his first group of rats, each of whom had lost about 5 per cent of cortical tissue, were apparently totally unaffected by the surgery, running the maze just as well as they did before! The rat with bigger chunks of tissue removed were slightly more affected, but even those with only half a brain left were still able to run the maze fairly competently. The loss of memory seemed to be somewhat proportional to the amount of tissue removed, but *not in any way to the area removed*! In other words, the mysterious engram did not seem to be located in any single spot, and Lashley was forced to conclude that it looked as though learning and memory were a function of the whole brain rather than just part of it.

As could be imagined, these findings were not well received by the conditioned reflex advocates and numerous attempts made to repeat them merely served to support these first findings. They were received enthusiastically by the Gestalt psychologists, who saw them as another example of their argument that the brain must be considered as an integrated whole and not as simply a bundle of conditioned reflexes.

The next strong—perhaps the strongest—anti-Behaviourist argument came from one of the Gestalt school founders, Wolfgang Kohler. His findings were disclosed in his important book, *The Mentality of Apes*, which can be bought in paperback and which everyone interested in psychology should read. Kohler, who was one of those clever scientists who manage to find themselves work in exotic parts of the world, conducted his critical experiments at the Primate Research Station in the Canary Islands. Here he watched with great interest the considerable learning skills of the higher apes, such as chimpanzees, and quickly arrived at the conclusion that conditioned reflex theory was not adequate to explain the scope of their intellectual behaviour. His most famous observation concerned the never-to-be-forgotten chimpanzee, Sultan. Kohler had noticed that chimpanzees will play about with sticks and similar devices in their cage, which they seem to use as toys. He then began to wonder whether the monkeys could ever be induced to use them as tools, so after placing potential implements inside Sultan's cage he then put a banana on the other side of the bars just outside its reach. After a bit of fruitless stretching the ape took one of the sticks and pulled the banana in. Now this in itself is a remarkable achievement, and if the ape had actually "worked out" the solution then it would have been suggestive of very much higher thought processes in the

animal than had hitherto been believed possible. However, it could be reasonably argued that the chimpanzee had seen some other person or animal using the stick as a tool and was therefore merely imitating, an action which could, with a bit of latitude, be thought of in behaviouristic terms. Kohler's next step put paid to that point of view. He placed in the cage several sticks of various lengths which could be fitted together to form a longer one, and, taking care not to show this technique to the monkey, again set a banana outside the bars but out of reach of any one single stick. After scratching round fruitlessly with various sticks and making aggrieved noises, Sultan began to play rather aimlessly with the sticks, occasionally fitting them together by chance. Suddenly Kohler, who was watching, saw the chimpanzee fit two sticks together, stare at them for a moment and then, as if making a decision, walk rapidly to the side of the cage and with this new long pole pull the banana in. The moment of comprehension when the ape "realised" what he could do Kohler wittily termed the "ah-ha reflex," a phrase which sums up beautifully a sensation we all understand and which was totally unaccounted for by the Pavlovian approach to the problem.

(g) Later Developments in Learning Theory.

You may have the feeling that Behaviourism, conditioned reflex theory, and its attendant experimental studies are more or less worthless and a hindrance rather than a help to the development of modern psychology. This is far from the truth. The point is that despite its vigorous self-confidence and contempt for "introspective" approaches to psychology, Behaviourism really only falls down through its pretentions to providing a *complete* theory of mind and brain. The Behaviourist experiments still work, and there is undoubtedly such a thing as the conditioned reflex, though one has next to no idea, from the physiological point of view, how it is laid down. Throughout the 1930s and beyond, psychologists supporting the Behaviourist position performed thousands of ingenious and often highly imaginative experiments to back up their ideas, these always being subject to counter-attack from the opposition, most of whom were followers of the Gestalt school. For years arguments raged over Kohler's "insight" study with the chimpanzees, and became even hotter when experiments claiming to demonstrate "insight" in lesser creatures, such as rats, were performed. Gradually, under intense pressure, the Behaviourist hard-line softened, the pretence that animals were no more than bundles of totally automatic reflexes was quietly abandoned. Once this occurred, and the Behaviourist method was put to work studying the functioning of living systems, then experimental psychology was set for a boom. One of the most significant features of the conditioned-reflex method, as exemplified by Pavlov's original experiments, was its usefulness for examining the nature of animal perception. Offhand one might wonder how it could be possible to tell what an animal sees, or more exactly, how fine is its capacity for perceptual discrimination. How could one find out whether a rat could tell the difference between a triangle and a square and between one colour and another? One can ask humans, but rats . . .? In the case of colours, what one could do would be to train the creature to respond to a red light, and then gradually alter its hue in the direction of another colour, say blue. If, before one had made much of a change in hue, the animal was ceasing to respond then one would know that it was detecting the change of hue. As for shape perception, the problem is even easier. In the very early days Pavlov conditioned his dogs to respond positively (*i.e.*, with saliva) to a circle, and negatively (*i.e.*, raising paw to avoid shock) when a rather angular ellipse was shown to it. Then he gradually made the circle more and more like an ellipse, and the ellipse more and more like a circle. Up to a point he got clear-cut appropriate responses, until the pattern lay somewhere in between. At this point the dog, poor creature, had a nervous breakdown, which wasn't too nice for it, but which told Pavlov a lot about its sensory and perceptual processes. While on these slightly macabre topics it might be worth mentioning that today dogs and rats have largely been supplanted for behaviouristic studies by a rather quaint choice of animal—the pigeon. The fact is that pigeons have been found to have quite remarkable powers of sensory discrimination and will peck away at buttons to get food or avoid electric shocks for hours on end. So good is the pigeon at telling the difference between patterns that it was even once proposed for a fantastic rôle in modern warfare—not its traditional job of carrying messages from spies but, believe it or not, as the control centre for a flying bomb! In the early days of guided missiles the kind of electrical equipment available was too bulky, cumbersome and unreliable to be easily put into flying bombs. This was particularly true about the equipment necessary to allow the bomb to select the correct target at the other end. One bright psychologist argued that the pigeon would be an inexpensive, compact, and reliable "pilot" for a flying bomb. The device, complete with pigeon in a little cabin, could be launched off on course and when the bird spotted the target (say an enemy battleship) which it had been previously trained to recognise, it would peck at the appropriate button and that would be that! So far as one can tell the idea was never implemented, which is probably a good thing for us humans—to say nothing of the pigeons. The idea might be described as one of the less fruitful to come from Pavlov's original idea and serves to remind us that psychology, just as any other science, can be properly or improperly used, depending upon circumstances and the individuals involved. But let us now return to the basic question—what is the actual nature of the learning process or the memory trace?

(h) The Nature of the Engram.

Earlier we said that there were three broad approaches to the problem of the memory trace, the neurological, the electrical, and the biochemical.

(1) *The Neurological.*

This is probably the kind of model that Pavlov would put forward today if he were alive. To understand it, remember that the conditioned reflex is essentially a chain of cells running from sense organ to motor-output (finger, paw, eye-blink, whatever). The cells of course were there in the first place, built into the animal from birth. It is the connections between cells, the links in the chain that are forged in the learning process. Fine, but how *are* the connections formed? Why one chain rather than another? A number of attempts have been made to solve this one, perhaps the most ingenious in recent years coming from the Canadian psychologist D. O. Hebb, an architect incidentally of the sensory deprivation experiments, and one of the first psychologists to be elected as a Fellow of the Royal Society. Hebb had been impressed by the discovery that nerve cells were frequently adorned with tiny bumps or knobs which tended to cluster at the points where the cell made contact with other cells—the *synapse*. There was even some suggestion from microscopic studies that these synaptic knobs tended to become larger and more profuse in the brains of more mature animals. Suppose, Hebb argued, that when a nerve cell was fired, it made contact with another via a synaptic knob and thus triggered the second cell into action. Suppose also that each time a synapse was bridged via a contact knob, this knob grew a little, as though through exercise, and thus made better contact. This, as time went on, would significantly raise the likelihood of a nervous impulse crossing at this point. If one can imagine the process repeated with a whole series of cells, then one can see that repeated firings would also increase the likelihood of particular chains of cells being activated, thus wearing a kind of path through the nervous system down which the neural impulse would "prefer" to travel. This Hebb suggested, could be the basis of the conditioned reflex—simply a con-

nection made progressively easier each time the route was travelled.

Hebb's theory attracted a good deal of attention when it was first published over 20 years ago, first because it seemed to fit the known physiological facts (such as they were) and second because it seemed to get over one of the awful difficulties facing any neurological theory of learning—the experiments of Lashley. Recapping briefly, these showed that the memory trace or engram for a particular task was not located in any one small section of the brain. Now Hebb's synaptic knob model implied that the initial path followed by a nervous impulse might be pretty random throughout the cortex, wandering here and there until, with repeated firings, it became established. This would quite possibly be a rather straggly chain and not necessarily the shortest distance between two points. Add to this the fact that the acquisition of a complex habit, such as learning a maze, would obviously depend upon thousands, possibly hundreds of thousands, of these neural links being established, and one can begin to see that Lashley's experimental results no longer seem to fly in the face of reason. Removal of any single chunk of cortical tissue would simply serve to remove a more or less random selection of the neural chains serving as the maze-memory. The more one took out, the worse the memory of the maze would be, but no single piece removed would ever eliminate the whole of the memory! To many people Hebb's theory, crude though it might be, fairly tackles the apparent paradox of Lashley's results. Others are not so sure. Its main default, the intervening years have shown, is that his nice ideas about the growth of synaptic knobs and their significance as contact points between cells are probably no longer valid. Today their function, and even their existence in the form that Hebb discussed, is questioned by many physiologists. Furthermore, for various reasons, there has been a strong shift towards the point of view that whatever form the learning process takes it is unlikely to involve changes in neural tissue—at least of such magnitude. To many psychologists and their colleagues, changes in the molecular structure of the cell must be involved. Before considering the evidence for this hypothesis, we need to examine briefly the Gestalt psychologists' attempt to account for learning and memory.

(2) *Electrical Field Theory.*

We have been talking of the Gestalt psychologists without pointing out an interesting fact—that the two principal founders were first trained as physicists! Jumping the broad gap between physics and psychology might seem a bit much, but Wolfgang Kohler was one who did it, and in doing so he injected into his theorising some of the ideas basic to his native topic. In the main this involved the concepts of electrical field theory. Without going into this in boring detail, it so happens that an electrical source, either in the form of a battery, a current flowing down a wire or whatever, spouts electrons in its immediate neighbourhood and these constitute an electromagnetic field. As the name implies, the most striking example of such a field is to be seen in the ordinary common-or-garden magnet, and the structure of the field can be observed by placing the magnet in a large mass of iron filings. Now Kohler and his friends argued that the brain was a potent source of electromagnetic energy and ought, therefore, to create a field within and around its tissue. The field would be powerful enough to modify incoming electrical input from the senses and to some extent impose its own pattern on it. Hence the Gestalt "laws" of perceptual organisation. This would be a two-way process, however, for sensory input, no matter how feeble, would impose at least minor changes on the structure of the cerebral field. Such changes, the Gestaltists argued, would constitute the basis of learning. It was a bold, if somewhat implausible point of view, and was treated as a serious alternative to the Pavlovian conditioned reflex ideas for at least a period. It had one or two gross defects, however, which even the Gestalt psychologists found worrying. In the first place, no kind of recording device seemed able to pick up any signs of permanent or semi-permanent electrical fields surrounding the brain. The EEG seemed to be a rhythmic picture of electrical change within, rather than of a static, powerful field highly resistant to change. Secondly, there is the odd data from electro-shock therapy. This much-maligned method of treating highly-depressed psychiatric patients relies on jolting the brain with a powerful electric shock, a not particularly pleasant process which nevertheless generally brings a notable remission in patients' symptoms. The point here is not to argue the pros and cons of ECT, as it is called, but to indicate that such tremendous shocks should be enough to seriously disturb any electrical fields, no matter how well-established, with presumably drastic effects on memory. In fact, long-term memory is totally unaffected by ECT, though, as the Gestalt supporters were quick to point out, there is short-term amnesia for events immediately preceding the electric shock. Thirdly, and finally, as it happens, there is the clinching experimental work of Lashley—not his tissue-removal experiment, but yet another in the catalogue of his remarkable repertoire. Lashley's procedure was as follows. He first taught a large number of rats a particular maze. Then he inserted in their cortex very fine sheets of gold leaf—a notorious destroyer of electrical fields. He then ran the rats through the same maze again, and found no evidence of any detriment in their performance. He also taught other rats the maze after they had had the gold leaf implanted, and found that they learnt it with no undue difficulty. After this work the Gestalt battle cry never seemed so loud or so convincing again. It is doubtful, actually, whether they ever really believed the electrical field theory, but it was a nice idea while it lasted.

(3) *The Biochemical Argument: Some Fresh Surprises.*

The memory capacity of the human brain is absolutely enormous. It has been calculated that it is quite capable of storing all the information ever fed into it—in other words there is no need for anything ever to be thrown out of store to make room for fresh material. The real problem in this case is not finding enough room to pump in information, but in finding a sufficiently efficient system to pull it out rapidly. Not only do psychologists believe that the brain has this almost limitless storage capacity, but they also have some evidence that all the information fed in, no matter how trivial, actually *is* stored! Some of the most exciting evidence to back up this belief has come from studies made during human brain surgery. These studies are a trifle gruesome and the squeamish might like to jump a paragraph or two here.

For a particular type of surgery—such as the excision of a brain tumour—it is necessary to remove a portion of the cranium and for various reasons it is advisable to perform the entire operation with the patient fully conscious. This is not so horrific as all that, for the brain itself has no pain-detecting cells and the initial opening can be made with a local anaesthetic. One or two scientifically-minded surgeons, notably Dr. Wilder Penfield, have taken the opportunity presented by this surgical requirement to perform certain experiments which have turned out to be of immense interest. With the patient's permission and co-operation, Penfield stimulated selected exposed portions of their cortex with tiny electric currents. Moving round from sensory area to sensory area he found that his tiny electrical stimuli provoked characteristic sensations from the patients. In the visual areas they might "see" lights, colours, etc., in the auditory areas "hear" sounds, and in the temporal lobes, get impressions of smells, taste, etc. Stranger still, Penfield found that certain parts of the so-called association areas of cortex, when stimulated, led to the patient recalling specific memories, often of apparently forgotten items. One woman got a vivid impression of herself in a kitchen of a former home and hearing the voice of her mother, long since dead. Others reported equally specific memories, sometimes with fragments of speech or

conversation attached, quite often of items which the patients reported they "hadn't thought of for years." One possible implication for this exciting work is, as we have said, that *all* information that has ever been put into the brain is stored as memory just in case it should ever be needed again. If this is so, then to most psychologists the idea that the memory trace is laid down in the form of major structural changes in the cell body (such as with synaptic knobs) is no longer tenable. There simply aren't enough cells to cope. But suppose that the engram is laid down *within* the cell, at sub-microscopic level in the form of, perhaps, the rearrangement of the specialised molecular structure. Since no one has ever got a really good look at a molecule, either in the nervous system or out of it, this might seem to be a bit of optimistic guesswork, but there is in fact some strange evidence to back the idea up. To consider this we must acquaint ourselves with one of the lowliest creatures capable of learning—the little flatworm, planaria. There is a good deal of argument about how far down the animal kingdom some form of learning can take place. Some workers even claim to have demonstrated memory mechanism in tiny single-celled creatures such as amoeba or its hairy cousin, paramecia, but you can be sure that any information stored was of the simplest and most rudimentary kind. It is when we get to the simplest form of worms, and planaria is one of these, that something closer to memory in the real sense can be clearly demonstrated. Typical of the kind of task which planaria manage, albeit with a good deal of intellectual effort, is to turn right rather than left at a little junction in order to get food or avoid an electric shock. They can also be conditioned to wince to a light being switched on when this is always followed by an electric shock—rather like Pavlov's dogs. Now planaria has the most rudimentary, almost non-existent central nervous system. It has a front end, shaped rather like an arrow with tiny light-sensitive organs in it, and which is clearly its head. It also has a back end which the charitable would call a tail. The question now is—in what part of the tiny body are memories laid down? The head would seem to be the most likely bet, though you might feel it would be hard to tell for sure. At this point the psychologist makes use of another of planaria's interesting features—its ability to regenerate tissue with ease. Take a knife and slice off planaria's tail and both ends swim away, one rather more efficiently than the other. Now in due course the head section will produce a new tail and—rather fantastically—the tail will produce a new head! Planaria can do other odd things too. Cut down the centre of its head without actually removing any tissue and in due course the two half-heads will regenerate into two full heads, producing a peculiar but rather neat looking creature. If one makes several flaps, instead of just two, you end up with lots and lots of heads on one body and get a very odd-looking planaria indeed. All this is very interesting, but the exercise has more point than this. In the first case, ask yourself a question; suppose you teach planaria a little maze and then slice the head into two. Now, of the regenerating heads, which has got the "memory" of the maze stored in it? Left; right; both; neither? Actually, the answer is both, and this should give some clue as to the answer to the next question. Cut a maze-trained planaria in half (head and tail) and let the respective sections develop again into a full creature. One would certainly expect that the head part plus its new tail would be able to perform its little task without much trouble, but what about the tail with its new head? The answer is that this too can "run" the maze. If this seems to be contradicting everything we've said about learning and the brain in general up to now, then in a way it is. We must remember that planaria is an exceedingly simple creature with no CNS to speak of and no nerve cells of the kind found in higher animals. The engram, wherever it is, is certainly not formed by the development of synaptic knobs or by the modification of complex electrical fields. Furthermore, as it is evidently stored in tail as well as head section, then it must presumably be laid down in most, if not necessarily all, of the animal's body cells. This is the point where the biochemists step in and argue that it is not the outside but rather the interior structure of the cell that is modified through learning. Odd indeed, but there is odder yet to come. Researchers got a collection of planaria and taught them a particular task—turning right in a simple maze and then took an equivalent number of planaria with no experience of this kind. They then collected the first group and whirled them round in a mixing bowl until all that was left was a homogeneous planaria soup, and repeated the process with the other, untrained group. They now fed the two kinds of soup (planaria will eat more or less anything that's hanging round) to different groups of totally untrained planaria and subsequently trained these in the original right-turn task. This produced an extraordinary result. The planaria who had been fed the soup consisting of trained planaria seemed to learn the maze task significantly quicker than those who had been fed the untrained soup! You will know enough about experimental psychology by now to realise that these results caused immense controversy, and a series of experiments were immediately launched by workers who had found the first result incredible. The controversy, incidentally, still rages as many of the attempts to repeat the experiments have not worked, but the original protagonists still maintain the validity of their results. It is not hard to see why the critics get so hot under the collar, for the implications of the findings, if valid, will throw into question just about every theoretical approach to learning to date. Since the planaria were thoroughly mashed up, no neural connections or even any formal kind of organisation within the system would remain to carry the maze information across to the cannibal planaria. Furthermore, one would have thought that the digestive processes of the cannibals would have completed the process of destruction. How then could the original maze habit, or traces of it, be possibly preserved and carried over? No one on either side of the argument has been able to offer up any convincing explanation, except that if the results are valid, then the maze habit, in the case of planaria at any rate, must be stored right down at molecular level—in other words at such a microscopic level that any mixing and digestion could have little or no effect on it. But even if the planaria results *are* valid, would the same thing necessarily apply to humans? Not necessarily, but if a process works for one living system it could in principle work for another, and we must remember our conclusion that the brain's enormous memory store suggests that modification of the neurone itself would be at too gross a level. It may well be that we shall find the brain puts down information in more than one way. There is reasonable evidence, for example, that many animals and humans are equipped with two kinds of memory store—a short-term, and possibly highly unstable one, and a long-term, more or less perpetual system. Information fed into our brains might go initially to the short-term store where it is filtered for relevance or general usefulness. If unwanted for some reason it might be eliminated, but if wanted, passed on to the longer-term system. Perhaps the short-term memory (the kind that allows you to "momentarily" remember a new telephone number) is electrical and the long-term biochemical, neurological or both. At this moment psychologists and physiologists across the world are concentrating on these exciting problems and perhaps, within the next few years, we shall have some new answers and, quite certainly, some fresh surprises.

(i) Unsolved Problems.

This section has attempted to raise some of the issues confronting psychologists in their attempt to solve one of the main mysteries of the brain—how information is stored and processed within it. Although a fair bit has been learned in the past decades, it has really served to show that the problem is much more complicated than the earlier workers ever imagined. Furthermore, you will have noticed that precious little has been said about how the information is extracted, for the very good reason that precious little is known about this. Curiously some interesting clues are beginning to come from the study of computers,

man's own specially-created slave brains. These are already capable of storing quite immense quantities of information, and engineers have been working steadily at improving methods of storing information and of getting it out in a hurry. In recent years the computer engineers and the psychologists have been tending to get together and pool their ideas—with some interesting results. To more and more scientists it has become increasingly obvious that the study of the brain is real ground for interdisciplinary contact, and that contributions to its study can come equally from psychologists, physiologists, physicists, engineers, mathematicians, educationalists, and so on. The recently formed Brain Research Association, for example, is composed of scientists from practically every discipline, with psychologists and physiologists, who are traditionally the kingpins in brain science, making up no more than 25 per cent of its ranks. Perhaps the really big problems in brain research will only come from multi-disciplinary teams of this kind. But this is something of a digression and we must now pass on from learning and memory to the lesser, but no less interesting problem of motivation.

IV. MOTIVATION.

(1) Why Does an Animal Do One Thing Rather Than Another?

This question aptly sums up the problem of animal and human motivation, an important facet of modern psychological research. As is always the case with psychology, perhaps more so than with other fields of science, what initially seem to be straightforward questions, designed to elicit straightforward answers, become steadily more complicated on close inspection. The odd, almost philosophical difficulties surrounding motivation are a good example. Why *does* an animal do one thing rather than another? Because it wants to, is the stock reply—a reply which actually doesn't get anywhere at all. To say that the reason for doing something is because the doer *likes it* is no explanation, merely renaming the problem so that it comes up in a different guise. It so happens that we tend to like doing the things we do, though of course this doesn't always apply. We certainly like to eat, but do we eat principally because we like it or because the food is essential to our survival? Perhaps the key is tied up here somewhere, and the rock-bottom cause for all animal and human behaviour lies in the need to keep the individual creature alive. Well, that will certainly do for food and water, but it clearly doesn't work for other common activities, such as sex. In the long term the survival of all living things depends upon sexual activity but animals certainly don't understand this and humans only found out the link between the sexual act and conception a millennium or so ago. And anyone who believes that people indulge in sex solely to allow the human species to survive is very naïve indeed. Now the situation gets even more complicated. It seems as if we make love because we like it, with the long-term result being that the species survives. But what can be the link, in physiological terms, between liking something and it "doing us good"? And just to complicate matters even more, supposing that we accept this link, how do we explain other common patterns of human behaviour? Why do some people like going to football matches or art galleries? Why don't they go there to eat the footballers or the paintings, and how is the survival of the human species helped by such practices anyway? Having muddied the issue thoroughly—or, rather, showed it up in its true light—we can now go on to see how psychologists have set to work to try to unravel it. They have not got very far, but they have got somewhere.

(2) The Mechanical Tortoise.

The first people to face up to the problems raised above were the Behaviourists. In their gallant attempt to explain human and animal behaviour in mechanistic terms they realised that they would have to account for the tendency of animals to set out to do things rather than simply engage in random, diffuse activity, and they thought this could be fairly simply handled. They were most anxious, of course, to avoid explaining different types of behaviour in terms of different goals—to suggest that an animal had got a goal in mind was to imply that it had a mind and furthermore some kind of "picture of the future" in it. To begin with they took the simplest possible form of mechanical analogy. Imagine a clockwork mouse, which when wound up runs across the floor. What caused it to do so? The clockwork and the energy tied up in the spring, of course, with its direction determined by such matters as the orientation of its wheels, the angle of the floor, etc. Anyone saying that the toy crossed the floor because it wanted to would be being silly. Similarly, the Behaviourists stated, one should be able to avoid the same kind of inference when observing the movements of a real mouse. If the response is that the real mouse can do a good deal more than just run across a floor—can squeak, change direction, avoid cats and eat cheese—then the reply in essence is that one could build a mechanical mouse to do that as well, provided one had the time and ingenuity. The more complicated and versatile the mechanical mouse the harder it would become to tell the difference between the two, and when one had two apparently identical mice, would one still talk about one "wanting" to cross a floor and the other doing it purely automatically? Was there an important difference anyway? Critics of Behaviourism argued that indeed there was a difference. The "real" mouse ate the cheese because it satisfied a need for the food, whereas the mechanical mouse, no matter how many bogus sounds of enjoyment it made as it munched the food, was merely going through an essentially meaningless mechanical process. This is a dangerous argument, for suppose that one decided to power the artificial mouse not by clockwork but by the combustion of cheese and made it so that it would stop when its inner store of cheese ran out . . . one would now have an artificial mouse with a "need" for cheese as great as that of its biological counterpart. If this seems an unlikely step to take, consider the case of Grey Walter's mechanical tortoise. In an effort to replicate some of the conditions of behaviour, the great English psychologist, Dr. Grey Walter of the Burden Neurological Institute, constructed a tortoise which exhibited some of the paramount properties of living creatures. His tortoise—a shell on wheels with no pretentions to looking like an animal—was powered by storage batteries which drove a motor allowing it to run around on the floor. Its movements were far from aimless, for it was also equipped with photocells in its head capable of detecting areas of light or dark. A series of simple switches inside were arranged so that when the tortoise's batteries were fully charged, the device would move towards dark areas of a room, finding its way underneath chairs and tables, carefully working its way round books, human feet, etc., placed in its way. With batteries low, a different switching arrangement would come into operation and the device would now tend to avoid dark areas and seek out light ones—in particular the light inside its "hutch" where a battery charge was conveniently situated. Once inside the hutch Grey Walter's tortoise would connect up to the battery charger, later emerging "replenished" to set out for dark places again! Here the Behaviourist argument emerges most strongly. It is not, of course, that Grey Walter had manufactured a living thing—no one is making that claim—but rather a matter of whether the tortoise's tendency to seek out its battery for recharging, etc., constituted a need in the same sense as does the real mouse's need for cheese. This is a big question which you will probably have to think out for yourself. In the meanwhile let's see how the Behaviourists attempted to translate animal behaviour into similar terms.

(3) Drives and Needs.

The Behaviourist position can be summed up as an attempt at describing animal behaviour in the

simplest possible way, and to do this they evolved the concept of "Drive." A drive is described as something which causes an animal to perform a particular act, and the ideal position, from the behaviouristic viewpoint, would be to find that all animal activity could be explained in terms of a limited number of drives. To begin with things looked simple and promising, for it appeared as if a drive could be thought of as something that promoted bodily well-being. For example, when an animal is short of food it is running out of power. This causes a sensation known as "hunger" which signals a bodily "need," and this in turn sets in motion a chain of activity which culminates in eating. When the food has been ingested, the need is satisfied, the hunger vanishes and the drive is reduced. The same argument applies to thirst and, with a bit of modification, to sex. In the latter case if an animal does not engage in sexual activity for a given period of time certain substances build up in the body, the hormonal system becomes unbalanced, etc., and a need builds up in the body, which gives rise to a drive. This in turn pushes the creature towards sexual activity with a suitable mate. Carry this on just a bit more and include a "need" to escape painful situations and you've practically got the whole of animal behaviour sewn up. What's more it is sewn up in a very convincing way because the needs and drives are not vague and ambiguous, but relate directly to vital bodily processes which if not operating properly will cause the animal's death. All animal behaviour could be explained in terms of a drive to (i) reduce hunger, (ii) reduce thirst, (iii) reduce pain, and (iv) achieve sex. To those who didn't want to talk about "achievement," which seemed to imply that an animal was actually setting out to do something, then the final one could be rephrased (iv) to reduce sexual tension. An animal in a state of need would be activated by some or all of these drives and would continue to "behave" until all drives were reduced. Protagonists of this delightfully simple point of view even showed how learning theory could benefit from drive-reduction ideas; a pattern of behaviour or conditioned reflex would be established, they claimed, if at its conclusion a drive was reduced. If no drive-reduction took place, then the behaviour pattern would not be learned. In the 'thirties and 'forties a number of mathematically inclined psychologists even attempted to express this in the form of sets of equations which looked enormously impressive on paper but which, alas, bore little relationship in practice to the way living animals actually behaved. For example, people soon realised that a bit of a problem emerged for an animal if all its drives were set at maximum, as it were, and all the appropriate drive-reducing stimuli were at hand. Take a rat, severely deprived of food and water, and place it in a cage with both available. What is it going to do first, eat or drink? Presumably it will be pushed in the direction suggested by the strongest drive. Using this as an idea it was decided that it ought to be possible to rank animal drives in order of strength by a simple test. Place a rat deprived of either food, water, or sexual activity in a box facing the necessary drive-reduction stimulus across an electrified grid. Now, how strong an electric shock is the rat prepared to put up with in order to fulfil its need? Experimenters found that thirst was the most effective stimulus, food next, and sex third. This was all fine until they found that rats satiated in all three modes would still occasionally cross the grid even when there was nothing on the other side! Now what kind of drive could be operating here? Furthermore, they found that an animal, again supplied with plenty of food, water, etc., would still run through a complicated maze and learn it pretty well, despite the lack of drive-reduction at the other end! Before long the theorists found themselves rather glumly proposing "exploration" or curiosity-reducing drives to account for the well-known fact that animals like to roam about all over the place. This, naturally, allows one to have a completely comprehensive theory of behaviour and learning in drive-reduction terms, but with the penalty of converting a simple, fairly sharply defined theory, tied closely to describable bodily requirements, into a complicated, diffuse, and far less convincing one. If any activity not explained in terms of the original drives can now be accounted for in terms of a reduction of an exploratory drive, then one has an "explanation" of the behaviour. But to many people's minds it is no better than those around before the whole concept of drives and needs was introduced. Similarly, there was a certain neatness and utility to the idea that a pattern of behaviour could be learned if at its conclusion a drive such as hunger or thirst was reduced. This neatness vanishes when we are told that an animal has learnt something else because its curiosity was satisfied, or the opposite. that it was not learnt because its curiosity drive was *not* reduced! Clearly the root of all these difficulties lies in the refusal of many psychologists to admit that a creature or a person does something or learns something because it likes it. Fair enough. We have already pointed out how subjective is the idea of an animal doing something because it "wants to," and the job of the psychologist is to try to define behaviour objectively rather than subjectively. What was clearly needed was some definable, describable physiological process which could correspond to "pleasure," and until this was found psychologists could proceed no further in the field of motivation. In 1954 experiments were published which gave them the green light.

(4) The Pleasure Centre.

The arrival of microelectrode recording techniques allowed numerous experimental studies of the animal and even, occasionally, the human brain in action to be made. In a prolonged assault on the inner intricacies of the cerebral cortex and lower control centres psychologists and physiologists began the elaborate job of mapping the brain, defining as rigidly as they could which areas were devoted to what function. In many cases the areas they stimulated seemed to be "silent," *i.e.*, provoking no obvious response from the animal. Others however, were more dramatically active. In 1956 the American James Olds and the Englishman Peter Milner were studying the responses of rats with electrodes implanted in what is known as the septal area of the brain, a spot beneath a body known as the corpus callosum. Animals stimulated with low voltage electric currents in this area seemed to behave in an odd way—almost as if they were enjoying the experience. For many years it had been known that stimulating the area known as the hypothalamus could produce symptoms of rage in animals, the creatures responding as though angered or threatened, the "sham rage" switching off immediately the electric stimulus ceased. Similarly areas had been found which when stimulated would cause dozy, apparently sleepy behaviour. Now here was something very different and Olds and Milner began to suspect that they had hit on something akin to a "pleasure" centre. To test this they designed a weird electrical circuit, surely one of the oddest ever to be seen in a laboratory. From the electrode in the rat's septal region a wire ran to the battery providing the electrical stimulus. In the rat's cage they placed a lever, and connected this to the battery in such a way that when the lever was pressed the battery emitted a single pulse, thus allowing the rat—if it wanted to—to stimulate this particular area of the brain. Although they had half suspected that the rats might occasionally give themselves a jolt in this "pleasure area," no one had anticipated the extent of the rats' involvement. All animals, once they had discovered the trick of pushing the lever, went into a sustained surge of lever pressing, keeping the activity up for literally hours on end. In fact there was some suggestion that they might have kept it up for ever, had not physical exhaustion sooner or later intervened. Given the choice of alternative levers providing food, water, or the chance to stimulate their septal regions, all rats reliably chose the latter, even those who had been substantially deprived of opportunities to eat or drink for some time. The lack of apparent satiation of the effect was one of the really odd things about the discovery. No human or animal appetite has ever been found which cannot be

satisfied, if only for short periods. Only where some severe pathology is involved, such as with a disease or brain tumour, do the normal appetites remain unquenched. But here was something quite different—an appetite which seemed to have boundless depths and which outrode any of the other paramount needs of the animal. It was for this reason that Olds and Milner hypothesised that they had hit on the centre in the brain which mediates the sensation which we humans know of as "pleasure." How surprising is it that some such centre exists? Not very. When we do something we like, be it eating, drinking, or even going to a football match, then the feeling of pleasure that we get must be matched by some parallel process in the brain, and it could well be that this is located in some convenient but specific centre. Olds and Milner, incidentally, found that their animals would very swiftly learn a task if they were rewarded by a session on the pleasure centre, and here perhaps another important point emerges. There has always been some evidence, though the matter is by no means settled, that learning was somehow improved if following the performance of the desired task, a "reward" such as food, drink, sex, etc., was given. The big question is, what kind of signal is given to the memory system to denote when something is to be permanently laid down? Olds and Milner appeared to have provided one possible answer, and one that would have greatly satisfied Pavlov, Watson, and their immediate successors, the reinforcing stimulus—the message that declares that something will be learnt—is a message that has passed through the pleasure centre. The validity of this idea is still uncertain, but it has the merit of answering an age-old question in reasonably simple fashion, and also of helping us towards the solution of an even more venerable philosophical one—the nature of pleasure itself.

(5) Emotion.

This is one of the most misunderstood words in the psychologist's vocabulary and is a source of endless confusion. The trouble is it means so many things to so many different people. To the psychologist, however, it has a fairly specific meaning and we must try to get some idea of what this is. Only by doing so can we avoid falling into such traps as to say, "Animals cannot feel emotions," or "Computers can never think because they have no emotions." First let's attempt to nail the word "emotion" to the wall and try to analyse it. When we talk of people being emotional, what exactly do we mean? That they tend to weep a lot, get easily angered? Sorrow and anger are emotions, that is clear. But is not love an emotion too? Do we mean that emotional people tend to fall in love a good deal? Or do we mean that their love is deeper than others—or perhaps shallower? Already some confusion is creeping in. Let's ask now how we know that someone is emotional, or in an emotional state. The answer is probably that they exhibit a characteristic behaviour pattern which allows us to judge. If they wave their fists, go red in the face and shout, then we might infer that they were angry. Of course they could be acting and merely pretending to be angry, in which case what is the dividing line between the real and the simulated emotion? The answer would seem to be that the latter was not accompanied by an internal *feeling* of a special kind, and this now tells us that there are at least two sides to emotion—subjective psychological state and an external, physiological one. In fact, psychologists find it convenient to consider three aspects. The first is the *behavioural—i.e.* the kind of activity in which the angry or otherwise emotional person engages. This is generally easily detected and is of the waving-arms-around variety. The second is the *physiological*, which consists of considerably more discrete behavioural signs, not always obvious to the observer but which may be detected by suitably sensitive instruments. The third is the *psychological* or introspective, and this refers to the "state of mind" of the individual when he is angry or whatever. This of course cannot be directly sensed by other individuals who rely on the angry person reporting to them "how he feels." How are these linked together, and what function do they serve?

(a) *The Behavioural.*

If you fire a pistol behind someone's back they exhibit a very characteristic response, the most common feature of which is that they jump some distance into the air. This may seem desperately obvious, but actually there is a good deal more to the response than that. High speed photography shows that all human beings respond to sudden loud noises by a highly predictable behavioural sequence, of which the jump is just one part, and which bears the name "the startle pattern." It includes a marked hunching of the shoulders, closing the eyes, baring the teeth, and raising the hands in the direction of the face. It doesn't take long to see that these actions, which occur reliably in all human beings, are not random and pointless but serve to help the individual respond rapidly to a dangerous situation. The jump is an alerting response, the eyes are closed to protect them, the hands raised in defence or perhaps to strike, the teeth bared possibly as a threatening or warning sign. Similarly, at a more common emotional level, the waving fists and loud voice of an angry man equip him to some extent for battle. And what of the tears and the cowering posture of a thoroughly frightened individual? Well, these in some way suggest to the aggressor that the battle is over and are signals to him to stop fighting. Men, being natural fighters, tend to do little in the way of crying and will generally scrap on until they are physically incapable of continuing. Women, on the other hand, who are not particularly strong or well-equipped to fight, tend to slip into weeping and submission rather easily, hence the well-known fact that tears are a woman's strongest weapon against a man. (This submissive pattern of behaviour fails dismally of course when the aggressor is a carnivore such as a tiger, when the one submitting is eaten, tears and all.) The very obvious facial expressions made by people in various emotional states led the great Charles Darwin to the view that the type of face made was a good index of what emotion the individual was in the grips of. To test this idea, psychologists took photographs of the facial expressions of people in various emotional states and then asked other people to try to name them. The results were poor, with few people doing better than chance. The only expression reliably recognised and correctly assigned to an emotion was a smile, and even this was occasionally confused with other emotional states such as pain, or even fear. The same experiment performed with movies yielded somewhat better results, and when sound was added results were again improved. The clinching thing, however, seems to be the setting in which the behaviour takes place, for people become very accurate at judging emotions when they see the surroundings in which the other people are behaving. Clearly the external signs of emotion, despite their immediate and rather obvious manifestations, are an unreliable guide to what is going on inside the individual's head. The same argument, incidentally, applies to animals, though somewhat less forcefully. Most animals give pretty explicit signs when they are angry or when they are afraid. One can even detect something suspiciously like guilt in the general pattern of behaviour of a dog which has done something it shouldn't. But can one really talk of a dog "feeling guilty"? If not—why not? Whatever answer you give will be quite as valid as any given by a psychologist.

(b) *The Physiological.*

The signs and signals we talked about above were all gross, obvious, and yet, as we pointed out, somewhat unreliable. To a large part they seem to be the outward manifestation of an internal process which at the same time serve a useful purpose, as when the startle pattern alerts the individual into a posture suitable for defensive or aggressive action. But what are the finer, physiological manifestations of emotion? These must obviously involve changes in the state of bodily and cerebral activity. Psychologists have pinned down no fewer than 11 distinct facets of human and animal behaviour which give a clear

index of changes in emotional states. To give some idea of the complexity of emotional behaviour we will look at each of these briefly.

(1) The first, and perhaps the most obvious, is heart-rate. The heart's job is to pump blood around the body and the blood provides the vital organ supply to the brain. The more intense the activity, the more oxygen is consumed and the more the blood needs to be circulated. It should be no surprise therefore to anyone to learn that as activity is stepped up, so heart-rate increases and vice versa. Furthermore, heart-rate tends to accelerate just prior to some important or exciting piece of activity, or even on merely thinking about it, and this means that we have here one index of emotional state. A device known as the electrocardiogram (EKG) can give a very precise picture of heart fluctuations and represents one objective way of plotting this information.

(2) We have already implied another measure, respiration. This increases more or less alongside heart-rate, and is a pretty good index of most emotions. Irregularities of breathing, including variations in the depth of breaths, are a particularly good index of nervousness as most people know and all this can be detected by a suitable instrument

(3) More or less hand-in-hand with the above come changes in local blood pressure and volume, the facial accompaniments of which—blanching or blushing—are only too obvious. These can be measured by a device known as the pleythsmograph, which is merely a version of the kind of device a doctor uses to measure your blood pressure in a routine medical examination.

(4) A somewhat harder emotional symptom to measure, but very characteristic of most emotional states, is muscle tension and its associate, tremor. In anger, rage, and other aggressive states muscles become tensed to be ready for rapid action and if this is carried too far we get trembling of the limbs—a familiar accompaniment of great nervousness or fright.

All the above are easily discernible indices, amenable to instrumentation but not depending upon it. The remaining manifestations are harder to detect, though just as valuable once one has caught them. Beginning with the most obvious we have:

(5) The pilomotor response, which is a hangover from the days when our ancestors had a good deal more hair than we do today, and which can be seen when a cat's fur fluffs out in rage or fear. In humans today we call it goose-pimples and it is often a precursor to the feeling of full-blooded fear.

(6) Even harder to measure is salivary secretion which is the kind of response Pavlov studied with his dogs. In anxiety or fear the saliva flow tends to be inhibited and we find ourselves with "dry mouths."

(7) An index of emotion which is particularly obvious to the individual is the change in gastrointestinal motility. Movements of the stomach and intestine are brought to a brief but definite halt in strong emotional states with a complementary, and often rather dramatic, surge back to action shortly afterwards. There are plenty of homely and slightly vulgar expressions to describe the consequences of this.

(8) There has been a recent rise of interest in the pupillary response as an index of certain types of emotion. The pupil of the eye tends to dilate in moments of anger or pain with slight dilation occurring during periods of "interest" in something. This has led some clever psychologists who work in the advertising profession to use this as an index of the relative effectiveness of different types of advertisement. All the subjects have to do is look at the subject matter while a recording camera photographs the pupils of their eyes from a distance!

(9) Because the endocrine or glandular system is active in emotional states the chemical constitution of the blood changes markedly as the hormones flow within it, but this index, while potentially useful, is of course abnormally hard to measure directly.

(10) Next we come to the so-called galvanic skin response (GSR) which is in fact nothing more than the electrical resistance of the skin. For various reasons, not properly understood, the resistance of the skin to an electrical current changes with most emotional states, tending to decrease as a function of the intensity of the emotion. This can be detected with a suitable instrument and meter and is perhaps particularly interesting because it is an automatic response which the individual is not consciously aware of. Connect someone up to a GSR meter, tell him that you are going to stick a pin in him and the needle will swing wildly. It is a very effective demonstration of an entirely involuntary response and is generally one of the first experiments that fledgling psychologists perform on each other in their laboratory classes.

(11) Finally there is the EEG, which we referred to earlier on (*see* Q5). The electrical activity of the brain does change with varying degrees of bodily activity, though what these changes mean is a matter for skilled interpretation.

(c) *The Psychological.*

You will have noticed that many of the above indices—stomach motility, muscle tension, etc.—have definite physical accompaniments which are only too obvious to the individual experiencing the emotion and it should not be too surprising in the light of all this that an emotional state markedly alters our physical and psychological feelings and sensations. But is this all there is to emotion? Can the age-old human passions of love and hate be reduced to permutations of salivary secretion, blood pressure, pilomotor response and electro-cortical activity? Put so baldly of course the answer is no. Love demands a partner, a setting, a trigger and some temporal span—as does hate. In humans these require the active participation of the complex computer we call the brain, and a background of education, social activity, and some awareness of goals other than the immediate. Nevertheless, the intense physiological and psychological changes which envelop us when we are in love, or when we fight in passion, contribute the better part of the powerful sensations we feel. But which of the three faces of emotion, the behavioural, the physiological, or the psychological is the real or most significant one?

The answer is that no single one predominates for emotion is a complex of all three. When the object of our emotion, be it love, hate, or whatever, is first encountered then mind and body combine to set the individual up for the optimum pattern of responses. This involves some permutation of physical change which, naturally, is reflected in psychological changes of mood. These in turn provoke outward changes on a larger scale which may involve combat or the ritual of love. If this description seems to debase the concept of human emotional response then this is a pity for there is no reason why it should. The powerful forces that thrust men into the numerous passions of the world would have no meaning were they not accompanied by potent changes in bodily state. The artistry that springs from these passions is no fraction diminished because we can identify the physiological and psychological changes that accompany and, to some extent, determine them.

It will have occurred to you that in this section on motivation we have drifted closer and closer to another of the critical areas that psychologists study—the nature of human personality. Psychologists know far less about this area than they would like to, but their century of scientific activity (a small span compared with the history

of the more traditional sciences, such as physics) has begun to pay off. In the next and final section we will take a look at what they have done, or have tried to do, in this most fascinating of areas.

V. PERSONALITY AND THINKING.

(1) What Constitutes a Person?

To many people this is the most important single question in psychology and indeed, perhaps, in the combined fields of science and philosophy. What is it that makes up that unique blend of psychological and physiological factors we call "personality."? The answer is, predictably, complicated and before we can even begin to consider it we must attempt to define the problems in the field. In the first place let's consider the most venerable and apparently simplest answer—a person is that thing in the head that thinks, feels, is aware of itself as an individual entity, and which controls a brain and body. This is the answer which probably fits best with the non-technical philosophy of the man-in-the-street and which matches also with a long-standing traditional view fostered by the majority of systems of religious belief. Put another way, it states that human beings are composed of essentially two parts. One of these is physical and consists of the body and its control centre, the brain. The second is non-physical, and is called the mind, soul, spirit, or some similar name. This is a separate entity which controls the body through its brain and while involved in this way must obey the laws of the physical world. It may, however, survive the death of its body (one of the most widespread of religious views of personality) and occasionally, as with telepathy, precognition, etc., may step outside to contact other similar minds in other parts of the world or even take a peek into the future. As we have said, this is an exceedingly widespread view of the nature of personality and it will be the one held by many who read this article. This is now the point where you could ask whether this view is acceptable to psychologists, and that is a fair and proper question. It requires, however, two separate answers. In the first place some psychologists, though certainly not the majority, accept this or some very similar view, but on an entirely personal plane. When they think as scientists, however, most are inclined to disagree with it. Nothing that has been uncovered in the history of experimental psychology, with the possible exception of the very dubious evidence for telepathy, suggests that the human personality is a separate entity to be considered in isolation from brain and body. Psychologists who choose to believe otherwise frankly admit that they do so on the basis of faith or hunch, and argue that even though the scientific facts appear to contradict their beliefs at the moment, perhaps in due course experimental psychology will uncover fresh new material to change the whole picture.

Does "Mind" Exist?

An increasing number of psychologists and brain scientists today take a hard-line on the "spiritual" view of personality, but does this mean that mind does not exist, as the Behaviourists strove so hard to prove? Certainly not. There is clearly a whole range of rich psychological activity which cannot be explained simply in terms of bundles of conditioned reflexes and the like. What seems to have happened in fact is that as animals have evolved via the remorseless processes of evolution, so more and more "power" has been given to the cerebral control centres. At some stage in the evolutionary ladder—it is very hard to say exactly where—the brain ceased to be a purely automatic device and some glimmerings of what we call consciousness began to appear. In the early stages, this probably merely took the form of a "switch" in the brain which allowed the creature to select from one or two alternative modes of action. This capacity would imply some system within the brain capable of making a "comparison" of the two modes and thus of "standing back from itself." Increase the complexity of the brain and its capacity to select, predict, and determine and you will see that the evolution of a higher control centre capable of "inspecting" ongoing activity will emerge. Thus could the thing we know of as consciousness develop. Incidentally, if you feel that such an abstracting, self-inspecting system could not be conceived in purely mechanical terms then you are wrong, for the latest developments in computer technology have been devoted to achieving this. But before getting caught up in arguments about whether computers could "think" (we'll tackle this briefly later on) let us just summarise the current approach to the problem that most psychologists accept today. Mind is a phenomenon which has arisen almost inevitably as brain complexity and power have increased, and its function is to select alternative activities and compute the consequences. Just as human bodies and brains differ in countless ways, so human minds, subtly moulded over the years from infancy to adulthood, differ too. The result is that the world is populated with a large number of human beings, united as a species, but each one an individual entity, compounded of body, brain, and mind. All three are equally real, equally important—and equally helpless without each other's company. Let us now take a look at the principal forces which serve to mould these individual entities we call people, and some of the essential ways in which they differ.

(2) Interplay of Heredity and Environment.

People and animals differ in a large number of ways, and are alike in others. We share certain features—upright posture, well-developed brains, etc.—with other primates, such as chimpanzees. We also share certain features—binocular vision, mammalian reproduction techniques, etc.—with white rats. We even have a limited amount in common—respiratory systems depending upon oxygen, need to ingest some kind of food, etc.—with creatures as lowly as the earwig, but nothing with cabbages or oak trees, except perhaps a dependence upon sunlight. Now what is it that determines these similarities and differences? The answer is summed up in the word heredity. Creatures of particular species mate with each other and hand on to their offspring, via the genes and chromosomes, the physical characteristics of the species (*see* **F31**). They may even hand on certain predetermined patterns of behaviour, which we have earlier referred to as instinct (*see also* **F38**). Broadly speaking, the lower down the phylogenetic scale, the more behavioural information is carried over via the genes, and the less flexible is the creature's ultimate behaviour pattern. Earwigs, for example, come into the world fully equipped to go about their simple business on this planet. They present almost identical faces to the world around them, and taking it all in all they change little from birth to death. Earwigs are largely the product of heredity, the principal forces which mould them lying in the genes of their parents and the incredible long history of their species stretching back for hundreds of millions of years. At the other end of the continuum we have human beings whose physical characteristics and a very limited number of behaviour patterns are inherited, but whose "personalities" and individualities (unlike the earwigs) change significantly throughout the span of their lives. These changes are the consequence of the impact of the environment on the flexible human brain, a flexibility which allows human beings to respond swiftly and intelligently to the changing hazards and opportunities of the world. It should be clear, therefore, that the basic differences that so obviously exist between the personalities of different people, reflect the experiences that each individual has had in his or her lifetime. See a newborn child and search for signs of its personality. You will look for a long time to no avail. But watch a child grow from infancy to adolescence and you will see the personality slowly building and emerging—more or less hand-in-hand with the young person's growing awareness of his own individuality, his strengths and his weaknesses.

Twin Studies.

Striking evidence of the immense influence that the environment has on us comes from the famous

studies of identical twins performed in America by Newman in the 1930s. There is a bit of confusion in most people's minds about what actually are "identical" twins as opposed to the ordinary, born-on-the-same-day variety. In the case of the latter—known as fraternal twins—what has happened to produce the happy event is that during conception two of the eggs in the mother have been fertilised and thus two babies are born. Without going into too much detail this means that two quite separate creatures develop, each being equipped with the random genetic mix that follows the meeting of the father's sperm with the mother's egg. The children, when born, may be of different sex, different colour hair, eyes, etc., and are likely to be no more alike than would be brothers or sisters born in different years or even decades. Each, therefore, begins with a different hereditary pattern, as determined by the genes. With identical twins a curious fluke occurs. By some process, *after* conception and *after* gene mixing has taken place, the fertilised egg splits, amoeba fashion, and two babies begin to develop—but both have identical gene patterns and thus, up to the moment of birth, can be looked upon as totally identical human beings. This weird identity is, as we all know, frequently carried on throughout the twins' lifetime, even though it is generally noticeable that the similarities become less marked with age. Now to return to Newman's experiment. Nineteen pairs of identical twins were found (a good deal of research was needed) who had for one reason or another been reared apart from an early age and had grown up in different environments. Newman found that while the adult twins maintained a striking physical resemblance, the personalities of the pairs seemed in many cases to have moved apart. In one case, the first of the pair had been successful in worldly terms, had acquired a college education, and was happily married with a stable family, while the second had been less fortunate and was leading a rather unsatisfactory life in an unskilled job in a working-class neighbourhood. Twin "A" seemed optimistic, good-humoured, and more dominant a personality, while twin "B" was morose, lethargic, and lacking in self-confidence. Similar observations were in general noted with other twins, particularly in cases where one of the pair had been reared in a more stable and economically more satisfactory environment. No better illustration of the relative influence of heredity and environment on human personality can be found than in studies of this kind. But is it only physical characteristics that are genetically determined? Is none of the psychological make-up of the individual "built-in" to him at birth? We can answer this by saying that twin-studies have shown that while personality is certainly modified by the environment, there is a good deal of evidence that intelligence is relatively untouched by normal environmental differences. Newman and his colleagues, for example, found that there was a higher correlation between the IQ test scores of *identical twins reared apart* than there was between *fraternal twins reared together*—a finding which suggests very strongly that intelligence, whatever that may be, is largely carried over in the genetic system and bequeathed to the individual at his birth. If this seems to be contradictory or terribly unlikely, then there is probably some confusion over the meaning of the word intelligence, and since it is one of the fundamental themes making up the fabric of human personality we will take a closer look at it.

(3) Intelligence and IQ Testing.

Psychologists have spent a good deal of time arguing about what exactly is meant by intelligence and it is not worth covering this battle-scarred ground again. One definition which makes a good deal of sense is "versatility of adjustment" which is another way of talking about the kind of flexible response to the environment which is so characteristic of humans. This of course means that we can talk of animals having some degree of intelligence, and most psychologists nowadays would agree that this makes sense. The only problem arises if one considers intelligence to be inextricably tied up with consciousness, thought, language, etc., which of course it is not. Certainly the ability to communicate in linguistic terms and to think in abstract modes are signs of a highly intelligent creature, but some degree of intelligence may be present without those traits. Probably one could even talk of intelligence being present in any animal that could modify its behaviour in response to the environment and repeat this behavioural response at some later date. This means, as you will have gathered, that intelligence is present in any creature that can learn, including our little friend planaria. It is of course a *very* limited form of intelligence and planaria would not come out with much of an IQ (intelligence quotient) if submitted to human IQ tests. The structure of these tests, incidentally, becomes comprehensible if one sees them as measures of human flexibility rather than of knowledge. The standard IQ test, which forms the basis of the much-reviled 11-plus exam, is an attempt at getting some idea of an individual's general flexibility rather than how much information is actually crammed into his head. Without getting involved in the educational argument here, the point is that a test of the child's inherent capability is more likely to give some index of his fitness for higher education than is a test of his knowledge, and this is what the IQ test attempts to sort out. Hence the relative uselessness of "cramming" to prepare for the 11-plus and the surprise results it sometimes produces. You may think you see a bit of a contradiction here. On the one hand we have said that intelligence, whatever it is, seems to be built in the individual and is something to do with his basic brain power. In this case why are new-born babies not fully intelligent at birth? The paradox is solved by saying that the peak of intelligence is not reached until the brain is fully mature (at about 18 years of age in homo sapiens) after which it begins to decline remorselessly with increasing age. Thus you will find that scores on IQ tests are "weighted" according to age. For very young children considerable allowance is made for age and their "raw" score is upgraded according to a standard scale. So too is the score for older people who inevitably score lower in IQ tests than do 18-year olds. Thus we find that a university professor aged 60 would produce a far lower raw score than a young student of equivalent intelligence—even though the venerable professor's head contains far more knowledge! If this seems odd, remember that it is the individual's potential and general flexibility that the tests are all about and not the depth of his fund of knowledge. The IQ test itself is a rather arbitrary affair and was arrived at in the first place by a group of psychologists selecting a bunch of questions which they felt best tested this rather elusive faculty of flexibility. They then arrived at a scoring system which achieved the result that if you tested a large number of people, drawn randomly from the population, their average score would equal 100. In fact this is exactly what an IQ of 100 means—it is the average score of the population at large. This has led to the sarcastic observation of one psychologist that intelligence was "that faculty that is measured by intelligence tests"! This is a witticism with some truth in it, but nevertheless the IQ has a practical value, notably as a sorter out of the bright from the dull in a situation where environmental or social backgrounds might have intervened to cloud the issue. The 11-plus is one such example, as is the fact that the IQ test taken prior to university entrance is the best-known predictor of success in final degree examinations—at least in the USA. On the other hand, as you may have suspected, social and cultural factors can influence IQ scores, thus suggesting that they are not as pure as might have been hoped. Tests conducted on white and black children in America in the 1930s, for example, showed a marked difference in IQ between the two racial groups—the whites coming out pretty clearly ahead. This was greedily seized on by racialists as demonstrating the innate superiority of the white children until it was pointed out that the selection of the two samples was faulty, the black children had been drawn from rural parts of the south while the whites came from the urban north. When a repeat experiment was performed, draw-

ing the whites from the rustic south and the blacks from the northern cities, exactly the reverse finding emerged, killing one age-old notion and at the same time highlighting the fact that IQ tests were vulnerable to social and cultural factors. Incidentally, for those who like to pursue racial arguments, it is interesting to note that the highest IQ ever recorded by standard tests, a shattering 200, was scored by—a young Negro girl. When considering the world as a whole, however, the fact remains that humans are very heavily divided from each other by a barrier potentially more difficult to surmount than those of race, class, or creed—intelligence. Furthermore the gulf is one that is particularly difficult to bridge because of lack of incentive on either side. A highly intelligent person generally finds the company of a rather dull person quite unacceptable, and the reverse is also true. Also, the differences between high and low IQs are likely to become more apparent in the coming decades as the old barriers of class, etc., which used to mask intelligence, dissolve. From this important aspect of human personality we now move on to consider the nature of one of the processes most characteristic of human brains—thought.

(4) Thinking.

We have suggested that personality is an amalgam of the various faculties which are associated with cerebral activity, and that variations in personality reflect variations in the individual's environmental history. Any creature with a reasonably flexible set of responses to its environment can thereforé be said to have some rudimentary personality, and many of us can detect this in our domestic pets. If this seems a peculiar notion then this is only because we have erroneously tended to think of personality as being a solely human trait, rather in the way that people dismiss animals in general as having no intelligence. But what is it that does distinguish us from other animals—do we differ merely in terms of the capacity and computing power of our brains? Probably the answer is yes, though it has to be recognised that the gulf is pretty wide. Yet if one looks at the cerebral equipment of, say, a chimpanzee one gets the feeling that there shouldn't be all *that* difference! Furthermore, if one comes closer to home and looks at some of our ancestors such as Neanderthal or Cro-Magnon Man, it is hard to account for the differences between their primitive lives and ours today. Certainly we exist 100,000 years later in time and it would be a bit pathetic if we hadn't progressed since then. But the same argument surely should apply to chimpanzees, who do not seem to have developed much in the same period, and the whole thing seems even odder when we learn that the now extinct Neanderthal Man had a cranial capacity (brain size) greater than that of modern man. One might explain the vast difference between Man and his rivals on the ground that he was the possessor of an immortal soul or divine spirit. Leaving this rather unsatisfactory explanation aside, let us try to find some other approach. The key lies in the capacity of humans for abstract thought—taking a step back in their minds and "introspecting." With this marvellous facility comes a natural talent to convert the results of these introspections into a code and communicate them to other members of the species. The communicating code is what we call language, and the introspective process, with or without a linguistic component, is known as thinking. Thinking of a kind probably comes in a good deal lower down, at the level where individual animals make "decisions," such as when a dog, faced with a fence blocking it from its food ultimately gives up trying to climb over it and simply walks round it! Kohler's chimpanzee Sultan was certainly indulging in something pretty close to thought when he fitted two sticks together to reach a banana. Nevertheless, there is rather good evidence that the development of a spoken language, such as only humans have, is the trigger which allows a kind of detached, abstract processing to go on and which has allowed us to build up an immense cultural heritage over the past 10,000 years.

(a) *Thought and Language.*

How much is thought tied in with speech? You will remember that Watson liked to call thought "sub-verbal speech" and there is some truth in this. Open your mouth and think the word "bubble." You will probably notice a kind of catch in your throat—which shows how the two processes are tied together. On the other hand, think of some visual scene—say a polar bear sitting on an iceberg. Most people can conjure up a pretty reasonable mental picture of scenes like this without too much trouble and certainly without saying vocally or sub-vocally, either the word bear or iceberg! Incidentally, if you *can't* get a mental image of this kind, don't worry, for about a third of the world's population can't either. This facility for producing "pictures in the mind" has puzzled psychologists for a century—in particular those who can't manage the images themselves, who are inclined to be a bit sceptical about the whole thing. Twist the topic round and consider the case of visual illusions and other perceptual anomalies. For example, take the kind where two lines, objectively the same, look to be of different length. No matter how much measuring with a ruler and how much you tell yourself that the lines are similar, your erroneous percept remains. Here perception and thought are *not* inextricably tied, which disposes of any lingering arguments that thinking was merely a consequence of visual, auditory, or some other input. Incidentally, the link between thought and language is suddenly coming under close study again, almost 50 years after Watson had originally tried to explain one in terms of the other. This arises from the young sub-science known as psycholinguistics, the founder of which is the American mathematician, Noam Chomsky. His thesis, rather seriously over-simplified, is that the structure of language can be used to give us a valuable key to the inner logic of the brain's operation. We can never hope to know directly how the inner mechanics of the brain work, he says, so we must look to find them reflected in some more directly observable process. Chomsky and his followers argue that in addition to its "surface" grammar (the kind of grammar we learn at school) all human languages have a deeper set of rules, closely tied in with the programmes which handle the deepest and most fundamental thought processes. Look closely at language, state and define the logic of the "deep grammar" and you have taken a peek at the brain's deepest secrets. It is an interesting idea, shared by many scientists who hold that similar clues can come from a study of dreams, but it suggests that the problem of defining thinking is even harder than we at first imagined.

(b) *Can a Machine Think?*

Yet another approach comes from computer scientists, who, concerned with devising computers capable of communicating in linguistic terms with human beings, have been taking a close look at these problems. From one of the pioneers of computer science, the late Alan Turing of Manchester, came a penetrating analysis of the philosophical problems of thought which reopens the discussion again from an entirely fresh angle. He did this by posing the question, "Can a machine think?" Turing pointed out that the almost universal response to this question was "No," but while people felt pretty confident in their opinion, they were seldom able to give a really good reason for it. Typical responses, when they were asked why a machine couldn't think, included, "because you can never get more out a machine than you put into it," "because machines have no souls," and "because only people can think." None of these arguments is valid. In the first place, it is only partly true to say that you can get no more out of a machine than you put in it, and in any case what has that to do with thinking? The second and third points are equally dubious. However, Turing realised that people had a built-in inclination to assume that thinking was a property of humans only, and as a computer engineer who hoped ultimately to see "thinking computers" developed, he was anxious to correct this impression. To do so he rephrased the question this way:

"Supposing that you continually built ever more clever computers, how would you know whether one had begun to think or not?" Pointing out that the only evidence we have about whether humans can think (apart from taking their word for it) is the nature of the conversation they have with us, he suggested that one would base one's decision on how well the computer was able to communicate and discourse. Assuming that the fact that the computer was a large metal object with glowing lights, reams of paper tape, etc., would bias people in their judgment of whether it was thinking or not, he proposed that the decision should be based on a simple game. Take one very clever computer which you have reason to suppose may be capable of thought and place it in a room "A." Now take a person in a room "B," and a third in a room "C." Connect up computer "A" and person "B" to person "C" by wires connected to teletypes (special typewriters which allow one to feed information into computers and allow them to respond). Person "C" doesn't know who is on the end of either teletype, "B" or the computer, but he proceeds to try to find out by asking them questions through their respective teletypes. Now if the computer was really dim it would soon give itself away by its dim answers, but if it was really clever it might easily fool "C" into thinking it was the person "B." One important rule of the game, incidentally, is that both "B" and the computer were attempting to fool "C," the object being not to be identified correctly as either human or machine. Now, said Turing, if the point comes where "C" cannot reliably and certainly decide which of his two communicators is which, then to all intents and purposes the computer "A" must be said to be capable of thought! This is really a brilliant approach to the problem even if it seems to be a bit obscure at first. What Turing was really saying was that the *real* evidence that thinking is taking place is evidenced by what the individual, be it human, animal, or computer, actually does, and not what it looks like.

Before leaving this enigmatic topic, consider two recent developments in this area:

(1) In at least two centres in the United States psychologists are engaged in dramatic and apparently successful attempts at "conversational" communication with chimpanzees. The husband and wife team of the Gardners at the State University in Reno, Nevada, have taught a chimpanzee to communicate using American sign language—a series of gestures with hand and arm. Their animals apparently are able to converse in sentences at about the level of communication of a three-year-old human child. Another researcher, David Premack at the University of California, has been teaching his chimpanzees to understand the meaning of special plastic symbols or "words." Using these the monkeys form sentences by placing the symbols on a magnetised blackboard, and have built up a substantial working vocabulary. They have even got to the stage of understanding and creating sentences featuring the conditional, for example "pick up the red cup *if* blue light is on," etc. Some of Premack's brightest animals are actually using a specially modified typewriter to generate their messages.

(2) Many psychologists and computer scientists believe that a breakthrough in the field of artificial intelligence—the creation of a robot or computer capable of "reason"—is imminent. The distinguished philosopher and statistician, Professor I. J. Good of the Virginia State University, has evolved the concept of what he calls the "ultra-intelligent machine" (UIM). This he defines as a computer capable of performing every intellectual function at least as well as a human being. Professor Good now believes that the first UIM will be with us before the turn of the century and possibly even in the 1980s. UIMs, he points out, have one special advantage over human beings—there is no theoretical upper limit to their intelligence. He believes furthermore that one of the first tasks that scientists will give to the UIMs to perform will be to set about finding ways of making themselves even more intelligent. This no doubt would rapidly solve all mankind's problems, though it might at the same time mean that the UIMs will decide that man has become redundant. And a species that becomes redundant, Professor Good reminds us, tends to wither away and die.

(5) The World of Inner Space.

We have constantly indicated that psychology is the study of behaviour—the activities of living creatures which respond to a meaningful non-random way to the vagaries of their environment. The key to understanding these patterns of behaviour is of course the brain, and within the brain itself the programmes which control and determine its actions. One important point which all who study the brain swiftly come to realise, and one which this section has attempted to emphasise, is that no living system can be considered as a mechanical assembly of different parts. Each, whether earwig, cat, or human being, is a complex, integrated system functioning as a unit. The further up the phylogenetic scale one rises, the more complex the system and the more sophisticated and elegant its mechanics. At the human level with mental activities and consciousness emerging as super-control systems, the study of psychology reaches its most fascinating point. Here too, it must be admitted, as a science it has made least headway. There are probably good reasons for this, some related to the intrinsically complicated nature of the mind, others to the attitude of the psychologists themselves. The early pioneering work of Wundt, Ebbinghaus, and others seemed to be setting psychology on course as a science in its own right. The work of Pavlov, immensely important and relevant as it was, served to weaken psychology as a discipline and shift its bias drastically in the direction of physiology. Psychologists themselves ceased to think like psychologists and instead attempted to convert themselves into second-hand physiologists, part-time mathematicians, and indifferent clinicians. This trend, which gathered strength in the 1930s, has persisted until quite recently when a growing disenchantment with the relatively meagre results stemming from the millions of behaviouristic experiments involving pigeons, monkeys, and rats has led to an inevitable swing of the pendulum. More now than at any time in this century is the principal creature for psychological study acknowledged to be man himself. Freud's fabulous and enduring insight—that the mind itself has two vitally important parts, the conscious and the unconscious, each integrated and yet strangely autonomous—is being treated with ever greater respect and understanding today. The realisation that human beings are controlled not merely by their conscious thoughts, wishes, and desires but also by dynamic forces of great power which are *not* under conscious control and barely available to linguistic analysis, is at last becoming a part of even the layman's view of mental life. The tip of the iceberg above the sea, as Freud pointed out, is that part of the mind which is under conscious control. Below the sea, massively enigmatic, lies the great bulk of the unconscious, the repository of the programmes which largely determine the behaviour of man. This is the zone, rich in mystery, which must ultimately be plotted by psychology and its researchers. This is the territory, glimpses of which we catch through the enigma of memory, the hallucinations of dementia, and in the misty drama of our dreams. The controversial English author J. G. Ballard has christened this territory "inner space," in contrast with the vast reaches of outer space that the first human astronauts are today beginning to explore. The explorers of inner space are psychologists, their colleagues in similar disciplines and all who journey along with them. At this stage their voyage has barely begun and, as with the astronauts, has no foreseeable ending. One thing is certain—it will be no less fascinating and no less rewarding. On the one path man seeks to discover his universe: on the other to discover himself.

THE MYSTERY OF HYPNOSIS

The phenomenon of hypnosis is one that has fascinated psychologists, physicians and laymen for centuries. The enormous amount of scientific curiosity in the topic however has yielded very little in the way of genuine understanding, and if the truth is known we're not much the wiser today about the oddities of the hypnotic state than were the sceptical scientists who witnessed Mesmer's demonstrations in Paris two hundred years ago. So little progress has been made in fact that while ten years ago psychologists and physiologists were coming to the view that hypnosis was a distinct, if poorly defined state of consciousness, today even this imprecise definition is considered to be suspect. Some experts are now even beginning to argue that it is not a phenomenon in its own right but merely a "state of mind"—and not a very important one at that! Book after book has been written about hypnosis, theory after theory has been propagated, and there will be very few readers who haven't heard marvellous and sometimes frightening stories about what can and cannot be done through the supposedly mystical power of hypnosis. Most of these are sheerest nonsense, but nevertheless dozens of questions pop into one's mind: Can one hypnotise a person against his will? Can one cure mental illness by hypnosis? Can one remember one's childhood, one's birth (and even before) through hypnotic age regression? etc. In fact it *is* possible to give fairly clear answers to the most commonly asked questions about hypnosis, and we will try to tackle some of them later on in the article. In the meanwhile the best way to get more than a superficial understanding of the phenomena associated with hypnotism, is to look at its history, its evolution and the way in which it has flirted with rational investigation for centuries and yet never quite been incorporated into the young but growing science of psychology.

The existence of trance-like states in human beings has been recognised for thousands of years, and whatever their origins these peculiar variations of consciousness have often been counted as highly significant. In primitive societies spiritual guidance is often given by an individual whose mental state is considered to be dramatically different from the normal, and often this state is induced by some lengthy, repetitive ritual such as a dance or chant. In ancient Greece, the pronouncements of the Delphic Oracle emanated from a priestess in what appears to have been a self-induced trance. More recently, in the mythology of the 20th cent., Spiritualistic mediums allegedly act as a bridge between the world of the living and of the dead after drifting into a trance-like state which may be induced by loud music, sustained deep breathing or other repetitive stimulation. Without discussing the merits of the messages emanating from the jungle witch doctor, the Delphic Oracle or Spiritualist medium it is fairly clear that Man has for thousands of years been aware of the fact that he can induce in himself or have induced for him a state of consciousness in which the "normal" laws of mind or psychology (however he interprets them) appear to be altered in some unusual way.

Sensational Work of Anton Mesmer.

No one however seems to have attempted to experiment systematically with these states until the latter part of the 18th cent. when the Viennese physician, Anton Mesmer, amazed Paris, and ultimately the rest of the world, with his remarkable demonstrations of the power of what he originally called "animal magnetism." Mesmer had been puzzled by the miraculous healing powers that supposedly surrounded certain individuals, and which apparently operated merely when the healer touched the inflicted person. Like most of the physicians of his day, he had read Paracelsus, the 15th-cent. alchemist who believed that the stars and planets radiated a beneficial and life-giving fluid throughout the universe. It occurred to Mesmer that the peculiar properties of a magnet, which mysteriously pulled objects to it from a distance, might be a manifestation of this universal vital force, and after conducting a few experiments he postulated the existence of a special variety of this energy which he called *animal* magnetism. To cure the body's ills, all one had to do was to induce extra amounts of this magnetism to enter the sick person's body—rather like filling up a motor car with petrol—and when this was achieved the patient would be cured. Just what kind of patients Mesmer cured at first is not known, but he was evidently successful for his practice grew rapidly and attracted the attention of the French Court. Before long group sessions were being held with patients sitting round a great vat of iron filings, which were supposed to amplify the magnetism, while Mesmer touched sufferers from time to time with his "magnetic wand". The "cure" was often accompanied by a strong convulsion, something like an epileptic fit, and this no doubt served to make the whole thing that bit more spectacular. Innovators in medicine are not generally welcomed by other members of their fraternity and before long a commission was appointed to investigate Mesmer and his achievements. The committee, which was a distinguished one and included the chemist Lavoisier and the American scientist Benjamin Franklin, took a long and cool look and decided that while there were indeed some impressive and genuine cures, notably of hysterical complaints, they were unable to accept Mesmer's explanation for them. "Magnetism minus imagination is nothing" their report dryly concluded, a comment which revealed a considerable degree of insight and is still largely valid today. Poor Mesmer, who unquestionably believed in his abilities and his theory, was more or less booed out of Paris and was later to die in obscurity. In the meanwhile the French Revolution intervened, which presumably allowed people to forget Mesmerism for a while and conveniently dodge the issue of just how it was that his many cures had been achieved.

Pioneers in the Clinical Use of Hypnosis.

One of the most peculiar features of the phenomena of Mesmerism was the strange "sleep" exhibited by some of the more deeply affected subjects. In this sleep, individuals became exceedingly relaxed, breathed slowly and appeared relatively insensitive to external stimulation. They could however carry out intelligent if rather sonorous conversation with the "magnetiser"—but not with anyone else! Phenomena so peculiar don't vanish simply because committees disapprove of them, and throughout the early part of the 19th cent. experiments with Mesmerism (most clinging to the animal magnetism hypothesis) continued to be conducted in various parts of the world. In London, University College was racked with controversy over the issue and the distinguished London physician, John Elliotson, was driven out of his teaching post for his advocacy of the principles of animal magnetism. In 1841 however an important turning point occurred when the Manchester surgeon James Braid, who had previously been quite contemptuous of "magnetism", experimented with his family and found that he could easily induce the trance state in them by asking them to fixate on a bright light in such a way that their eyes became tired. Braid came to the conclusion that what he was witnessing was not the effects of some peculiar magnetic field but rather a special mental state, principally caused by a kind of optical fatigue which was in some ways close to normal sleep. With this in mind he threw the words "Mesmerism" and "Magnetism" out of the window and substituted "Hypnosis"—derived from the Greek word for sleep. It was a slightly unfortunate decision for the sleep-like connotations of the word have persisted, despite the growing conviction of most psychologists that the hypnotic and sleep states have virtually nothing in common.

Braid's work, which included experiments in the anaesthetic or pain-relieving virtues of hypnosis, was coldly received in England but was picked up with enthusiasm abroad. His acknowledged reputation as a scientist blew away some of the magical and mystical overtones of the topic and serious research got under way in Paris under the direction of the outstanding French neurologist, Charcot. Even further afield in India, the government surgeon Dr James Esdaile performed literally hundreds of sensational operations, many

apparently painless, using hypnotism in place of an anaesthetic (general anaesthesia had not yet been invented). For those who like details, one of the operations involved the removal of a gigantic tumour, *over two metres in circumference* and weighing 46·5 kg from a young man who showed no signs of pain through the course of the operation. Some of Charcot's work in Paris, incidentally, was centred on the anaesthetic problems of hypnosis, but the invention of simple general anaesthetics, such as ether and chloroform, at around about this time dampened enthusiasm for this approach. Charcot then turned to study in a scientific way the various methods of inducing hypnosis and he was also the first to point out that there were in fact a number of levels, varying from a preliminary state of mild suggestibility to a full-blown somnabulistic trance. Charcot also found that he could apparently cure certain patients of their symptoms—hysterical blindness, paralysis, etc.—under hypnosis and could even induce the same symptoms in normally healthy people. As can be imagined these clinical demonstrations of making the lame walk and the blind see attracted the attention of doctors from all over the world, and on one occasion he was visited by a young Viennese doctor who was more than usually intrigued at the apparently magical disappearance and reappearance of symptoms. His name was Sigmund Freud and his interest in hypnotism and the extraordinary phenomena surrounding it was a forerunner of his great insights into the nature of unconscious mental processes.

Freud in fact carried the principles of hypnosis back to Vienna and began to treat some of his psychologically disturbed patients, using Charcot's techniques. He immediately made an important discovery: the patients' symptoms vanished but, unfortunately, almost always returned within a matter of days or weeks. Freud swiftly realised that this was an essential and serious weakness in the method, and he slowly lost interest in it, using it in later years more in an effort to unlock his patients' repressed memories than as a general-purposed symptom remover. Here it had some successes, though even these were limited and psychoanalysts as a whole remained doubtful of its utility. Part of the problem was that those analysts using hypnosis in their practice became very suspicious of the authenticity of many of the "repressed" memories which were dredged up while their patients were in "trance". So although in many ways the late 19th cent. was the golden age of medical hypnosis, the truth of the matter is that while resistance to the phenomena on the part of scientists and physicians has decreased steadily since the time of Braid, its usefulness in general or psychological medicine has turned out to be very limited. Its great achievements, if one can describe them as such, have come in the way in which it has captured popular imagination and in launching some eccentric and ludicrous fads, such as the "Bridey Murphy" mania in the 1950s when people believed that through hypnosis one could be led to remember details of one's "past lives"!

Present-day Views.

What then is the status of hypnotism today? To begin with, the picture has been simplified enormously from the days when it was believed that a hypnotic trance was induced by some invisible but nevertheless physical force of the animal magnetism variety. It's now clear that hypnosis is a state of mind—perhaps even attitude of mind would be better—in which the hypnotised individual gently slides into a greater state of psychological rapport with the hypnotist. This state is one in which, firstly, his attention is focused more and more closely on the hypnotist, to the exclusion of the rest of the world and, secondly, in which he becomes more and more prone to accept and agree with the suggestions and statements made by the hypnotist. In other words, hypnosis is now looked upon not as something which is switched on and off like a light, but rather as a continuum which begins as soon as one human being *pays attention to* and *accepts a suggestion from* another. It is at this level of the continuum that the forces of commercial advertising click into operation, and a little further along the scale come the techniques of political indoctrination. To some extent even a love affair represents a kind of two-way hypnotic state with both parties unquestionably accepting, believing and obeying the other. In hypnosis, as Braid, Charcot, Freud and present-day exponents know it, the "mental love affair" of course operates on a one-way basis. The hypnotist sets out to establish rapport and suggestibility. First he gets his subject into an "agreeing" frame of mind—"Your arm feels heavy"; "Your eyes feel tired," etc., which when repeated sufficiently will carry some conviction (particularly as arms and eyes do get tired from perfectly natural causes!). From here the boundaries of agreement are extended. The subject is told that he feels tired that he can hear no voices other than the hypnotist's, that his limbs feel stiff, loose or whatever. He may even be told to hallucinate or to perform some unusual act, and he will do so as long as he is prepared to accept the hypnotist's suggestions, *and no longer*. The important point to realise is that all hypnotic phenomena are a matter of acceptability. No human being, no matter what "level of hypnosis" they have achieved, can be made to do something that they intrinsically do not want to do. Professional hypnotists have long learned that this is so, and when public demonstrations are given, the hypnotists are always careful to guide their subjects along pathways which they know they will be happy to use. To that extent therefore the hypnotic state is only a valid one as long as agreement exists between the hypnotiser and the hypnotised to maintain it.

At first thought this may seem to make the whole thing farcical or fraudulent or both, and it would be so if we were witnessing a conscious and deliberate piece of play-acting on the part of the hypnotised subject. Such a view does little justice to the enormous complexities of human consciousness and personality and also fails to account for some of the weirder phenomena of hypnotism—the apparent insensitivity to pain, the apparent sharpening of memory, the apparent rejection of "bad habits", the apparent cures of many minor psychological complaints. Even more at odds are such quite remarkable phenomena, rare though medically attested, in which blisters may be raised on the skin when a deeply hypnotised subject is told that he has been burnt. However strange though these phenomena may seem, it must be realised that all human beings appear to have some intrinsic ability to control pain and that this is a matter of psychology rather than physiology. At one end of the continuum, for example, a brave man sufficiently well motivated will endure appalling physical torture rather than betray, say, his country or his comrades; at the other end of the scale a neurotic hysterical person may experience agonies from a condition which should only cause a "minor headache". As far as changes in the external appearance of the body are concerned, it has long been known that the condition of the skin's surface, to take the most obvious example, can be changed rapidly—blushing, rashes, etc.—with mental stresses. The point here is that all the phenomena experienced in the hypnotic state are phenomena which the individual could achieve or create if he were really prepared to set his mind to it. Memory may be improved but not to the point of perfect recall; pain may be relieved but not totally eliminated and in any case no more so than as the consequences of a placebo drug; hysterical blindness or paralysis may be alleviated, but hypnosis cannot restore sight to a damaged retina or to an atrophied muscle. Hypnosis does not induce telepathy, levitation, an increase in intelligence, an abnormal life span, greater fertility or any other attribute of which the individual is not inherently and in principle capable. What hypnosis does seem to do is to steer the individual, as the result of a series of "agreements" with the hypnotist, to exploit some of his normal potential and it is here that its limited benefits are most obvious.

To summarise then, the view of hypnosis which is gaining the most rapid acceptance at the moment is that it is not a special *state* of mind with *abnormal* properties, but rather an *attitude* of mind in which *normal* properties, previously latent or suppressed, are brought to the fore. Astonishing though it may seem to those who have come to

believe that hypnosis is a vital faculty or phenomenon of the mind, the truth is that an increasing number of psychologists today are even disputing the fact that it is a phenomenon in its own right at all. Many even believe that it may well fall back in status to nothing more than an interesting blind alley in the history of the evolution of psychology. The fact that it appears to work at all, they argue, is a tribute to the depth of man's interest in his mystical powers, and in turn to the power of his own mind to dress up a fiction with the clothes of reality. This may be a radical view but it is one rapidly growing in popularity.

Questions and Answers.

The following are some of the most common questions asked about hypnosis and relevant phenomena.

Can someone be hypnotised against his will?

No. Hypnosis, as understood today by therapists, is a state or attitude of mind in which the individual responds readily to suggestions put to him by another person (the hypnotist) provided that these are acceptable to him in principle. All hypnotists are aware of the fact that even the best hypnotised subjects have " suggestibility blocks ", where presumably issues of moral or ethical significance to the individual are involved. A hypnotist may induce a person to make a fool of himself before a group, but he will not be able to do this with anyone who has not got a prior inclination of this kind. It is quite untrue that a hypnotised individual could be ordered to kill or commit a crime against his will.

How useful is hypnotism in curing bad habits?

It appears to have some limited use in assisting people to throw off such habits as smoking, nail biting and even occasionally excessive drinking. The prerequisite however is that the individual, before the therapy can work, must really want to be rid of the habit. The task of the hypnotist is therefore to guide the individual, by a series of suggestions, to the realisation that he does have it in his power to cure himself. Hypnosis has been successful on occasions in treating such trying problems as enuresis (bed wetting), but probably because it increases the sufferer's motivation and focuses his attention on the problem and his own inherent ability to control his bladder.

Can hypnosis be harmful?

Probably no, though it would be difficult to lay down a hard and fast rule. The main dangers of hypnosis may lie in (1) the effect on the relationship between the hypnotist and his subject, and (2) in the effect of hypnosis on the subject's image of himself. In the first case it would be theoretically possible for an unscrupulous hypnotist, by choosing his subjects with care, to make them highly dependent upon him for emotional support. If the hypnotist was being paid for his services, then he would have a financial hold over his subject—but no more of a hold than an unscrupulous psychologist or psychoanalyst could achieve over certain of his own patients. In the second case, an unscrupulous hypnotist could, for one reason or another, decide to amplify the weak points in his subject's personality and character, by consistently drawing attention to them, and at the same time playing down the most positive aspects of his personality. In this way the individual might suffer a dramatic loss of confidence in himself and his ability to cope with the problems of life.

What kind of person makes a good hypnotist?

There are three main essentials: Firstly, one must believe implicitly in the phenomenon, even if one is not sure what lies behind it. Secondly, one must have absolute confidence in one's ability to hypnotise. This can only be achieved of course by experience, and most hypnotists " discover their abilities " by practising on friends and seeing how easy it is to do. Thirdly, one must learn some of the techniques and skills of inducing hypnosis, and the signs or " symptoms " which tell that one's subject is entering into the hypnotic state.

What are the techniques of inducing hypnosis?

These rely on inducing a suggestible state in another person which means persuading him to agree with a series of statements which are made about his psychological and physical state. Traditionally this begins with statements of the " Your eyes are feeling tired," " Your arm is feeling heavy " variety with which, after a number of repetitions, it is almost impossible not to agree! From then on the statements requiring agreement become progressively more ambitious until the hypnotised person agrees that he is " asleep, " " paralysed, " can hear only the hypnotist's voice, etc. The limits of hypnosis are reached at the same time as the limits of " agreement " by the subject are reached.

How can one tell when someone is hypnotised?

The hypnotic state begins the moment that the first agreement with the hypnotist's statement is made. A skilled practitioner of the art, given a group of subjects, will give a few simple commands and as there is considerable human variability, for a number of reasons, in responsiveness, he will soon be able to tell who are likely to be the most productive individuals. In a public demonstration he will eliminate those showing resistance and concentrate on one or two of his " best " subjects, who within a matter of minutes will be in a hypnotic trance or sleep, or behaving in an eccentric fashion at his request. The sole criterion for establishing the existence or depth of the hypnotic state is how readily or " naturally " the individual agrees to the hypnotist's requests.

Is hypnosis like sleep?

Not in any way, except in the origins of its name which comes from the Greek " hypnos " meaning sleep. Recordings of the electrical activity of the brain, the EEG, show that even when subjects are in the so-called hypnotic trance or " sleep " the cerebral patterns are more or less indentical with those of the waking state, and are quite unlike those of the sleeping brain.

What sort of people use hypnosis today?

Many physicians and psychologists use hypnosis in the experimental sense in an attempt at pinning down its basis and relationship to other mental states. It is occasionally used in psychotherapy or psychoanalysis to induce patients to talk about aspects of their personal life or psychological conflicts of which they are extremely ashamed or inhibited. It is occasionally used by dentists, particularly to allay the fears of patients who are abnormally anxious about treatment. It is used widely in many forms of unorthodox psychotherapy, often by people without psychological or medical qualifications, and most claims of remarkable " cures " come from these sources. Such cures are often very short-lived. Apart from in its experimental role, the truth of the matter is that hypnotism is rarely employed in orthodox medical and psychological practice.

Are women more easy to hypnotise than men?

There is some evidence that women are more suggestible than men and may be hypnotised more readily. It is also a fact that easily the majority of people practising hypnosis are men, and this may reflect the dominant role of the male in our present society. A substantial number of women have been brought up to accept this relationship and not to question statements or commands

given by men. Such an attitude of mind will certainly enhance the powers of the male hypnotist with female subjects. In many parts of the world —in particular the Far East—where female servility is even more deeply entrenched, there is some evidence that women are exceptionally readily hypnotised. It is also perhaps worth noting that some of the most dramatic successes of hypnosis were achieved in the early 19th cent. with British doctors working with native Indian patients, where the enormous authority of the members of the privileged class greatly assisted the phenomena.

Can hypnosis remove pain?

This is an exceedingly difficult question to answer for the phenomenon of pain is far harder to define than one might think. High variations in tolerance to pain exist between people, and there is much evidence that hypnosis does not remove the pain itself but leads the individual into a state where he can overcome it, deny it or "live with it." One of the strangest features of hypnotically induced anaesthesia concerns the fact that a patient being given minor surgery or, say, a woman being helped to childbirth when in a hypnotised state, will frequently tell the hypnotist that they feel no pain, show no external signs of it, and yet will afterwards tell other people that the pain was present. This dichotomy is still very mysterious, but no doubt the key to understanding the basis of hypnotism is somehow tied up with it. Hypnosis, as an aid to performing "painless" surgery, immediately fell out of favour with the arrival of general anaesthetics in the mid-19th century.

Is there such a thing as age regression under hypnosis?

A skilled hypnotist will induce a suitable subject to describe vivid memories and details of earlier parts of his or her life, and some of these details frequently seem to have previously been forgotten by the subject. The difficulties of providing proof of the fact that these (a) are real memories, and (b) had really been repressed or forgotten, should be obvious, and most psychologists today believe the hypnosis itself cannot drag from the memory any facts that would have been inaccessible to any other deep-probing strategy in which hypnosis was not invoked. Accounts of people who have recalled their birth through hypnosis are probably nonsense, and those which claim that they've been able to remember "past lives" are simply absurd. A particularly good example of the creation of a silly myth of this kind was the "Bridey Murphy" saga of the 1950s, already mentioned, which just goes to remind one of the gulf between serious and amateur investigations of hypnotism.

Can one hypnotise oneself?

One can certainly induce peculiar mental states in oneself by meditation, mystical exercises, and by a number of rituals recommended in self-hypnosis manuals. Whether such states are of any significance or of any value to the individual experiencing them is very arguable, but if people enjoy them or believe they benefit from them, then that is probably sufficient justification. Occasionally, by the induction of such states, individuals claim to have been able to break themselves of a bad habit, attain a relaxed state of mind, overcome some personal problem or whatever and frequently this is referred to as hypnotising oneself. People who have successfully rid themselves of habits by such means may well be proud of the fact, but in all probability they would have been able to achieve the same result by strength of mind and perseverance. There is no danger that standing in front of a mirror and making mystical passes will send one to sleep—except through boredom perhaps.

Can hypnosis induce telepathic powers?

Most scientists are even sceptical about the existence of telepathic powers in any case, but even if they did exist there is no reason in principle why they should be more prevalent in the hypnotic than in the normal state. One of the pioneers of medical hypnosis, the London physician Elliotson, was thrown out of his profession in the early 19th cent. because he claimed that hypnotised subjects showed telepathic and clairvoyant ability. Claims of this kind, viewed with great scepticism by most scientists, have continued right up to the present day. The most recent exponent of this argument was the late Professor L. Vasiliev, a distinguished physiologist of Leningrad University and one of the few scientists in the Soviet Union to have taken an active interest in parapsychology. He claimed to have shown that ESP was facilitated by hypnosis and published his results in England in the late 1960s.

What is post-hypnotic suggestion?

This involves the implanting of a command or suggestion in the mind of a hypnotised subject, with the requirement that it is executed at some later time when the subject is in a normal waking state. For example, a person may be told that he will telephone someone at a particular time or, at a less trivial level, as in hypnotically assisted childbirth, that a woman will feel no pain when the child is being delivered. The phenomenon is a curious one but it has no mystical connotations and merely implies that the individual is still in a "state of agreement" with the hypnotist to obey the previously implanted suggestion. He does not go into a "trance" to carry out the command, but merely interrupts whatever he is doing in as normal a way as possible. Once again it must be remembered that a person under post-hypnotic influence cannot be induced to do anything which is foreign to his wishes or nature, and there is no evidence that post-hypnotic suggestion can induce any strictly abnormal psychological or physiological feats.

Is there such a thing as mass hypnosis?

In the popular understanding of the phrase, the answer is No. It is not possible for a man, by some hypnotic technique, to put his whole audience into a hypnotic trance or to make them all behave in a certain way by merely willing them to. There are ways however in which a clever individual, equipped with some of the techniques of hypnosis and some understanding of psychology, can lead an audience along a particular direction of thought by the skilful use of words. Professional politicians are adept at this of course (though they frequently don't realise what they're doing!), and they may rouse an audience to unusual enthusiastic support for their views. It is significant, however, and an important factor in understanding the limitations of the hypnotic method, that no matter how skilful the politician (or hypnotist) he is unlikely to be able to do much with an audience which is not in pretty general agreement with his views in the first place. Another example of "mass hypnosis" can be seen in the exploitation of the media by advertising agencies.

GUIDE TO EDUCATION

The aim of this section is to present a brief yet comprehensive outline of the education system in England and Wales from nursery school to university.

TABLE OF CONTENTS

I. School Education 3–5

- The Nursery School
- Primary Education
- Secondary Education
- Special Schools
- Independent or Direct Grant Schools
- Public Schools
- Other Independent Schools
- Preparatory Schools

II. Further and Higher Education 5–8

- Further Education
- Higher Education
  - Universities
  - Polytechnics
  - Colleges of Education
  - The Open University

III. Some Controversial Issues 8–9

- Children's Growth and Development
- Streaming and Family Grouping
- Caning
- Standards of Reading
- Selection

IV. General Information 9–10

- School Examinations
- Religious Education
- School Curricula
- Special Services
- The Major Reports

V. Administration and Government of Education 10–11

- The Government
- Local Education Authorities
- School Administration

Useful Addresses 11–12

- Higher and Further Education

GUIDE TO EDUCATION

On the most recent estimates the education service in England and Wales costs the taxpayer some £2,679 million a year (6·5 per cent of the gross national product), and comprises 28,847 state schools maintained by local education authorities), with more than 9 million pupils and 382,000 full-time teachers, as well as 2,829 independent or direct grant schools with 527,877 pupils. There are also 1,019 special schools for handicapped children with 90,361 pupils.

Compulsory schooling starts at five and ends at 16, although the Government has announced plans to enable most children to attend nursery schools on a half-time basis from the age of 3 after 1974. After 16, attendance at an educational institution is voluntary. The provision includes universities, polytechnics, colleges of education (still devoted mainly to the training of teachers), and colleges of further education.

1. SCHOOL EDUCATION:

The Nursery School.

Until the new plans (see below) are implemented much of the education for children under 5 is in the private sector, where fees are paid. No fees are payable in the State sector, where there were about 500 nursery schools, and 2,000 nursery classes in primary schools, with 113,000 pupils, more than half attending part-time. About 220,000 children were in infant classes, mostly attending full-time. Yet only a third of all 4-year-old children—and 5 per cent of 3-year-olds—were attending nursery schools, a level of provision much lower than the rest of Europe.

In its White Paper, *A Framework for Expansion*, published in 1972, the Government said that it was launching a new policy for nursery education. "the first systematic step since 1870," when education was made compulsory at the age of 5. Among the arguments advanced for the new policy, in the Government's own words, were:

> There is now considerable evidence pointing to the importance of the years before five in a child's education—and to the most effective ways of providing for the needs, and potential, which children display at this age. The Reports of the Central Advisory Council, under Lady Plowden and the late Professor Gittins, based practical proposals upon these ideas. They recommended that most needs could be met by part-time nursery education and that places should be provided for all three- and four-year-olds whose parents wished them to attend. The Plowden Council estimated that provision for 90 per cent of four-year-olds and 50 per cent of three-year-olds would be adequate to meet demand.
>
> The action the Government now propose will give effect to these recommendations. Their aim is that within the next ten years nursery education should become available without charge, within the limits of demand estimated by Plowden, to those children of three and four whose parents wish them to benefit from it.
>
> The value of nursery education in promoting the social development of young children has long been acknowledged. In addition we now know that, given sympathetic and skilled supervision, children may also make great educational progress before the age of five. They are capable of developing further in the use of language, in thought and in practical skills than was previously supposed. Progress of this kind gives any child a sound basis for his subsequent education.
>
> The opportunities which the new policy offers for families living in deprived areas—both urban and rural—in bringing up their young children will be particularly important. There, as elsewhere, the Government believe that provision for the under fives should build on, not supplant, parents' own efforts.
>
> The extension of nursery education will also provide an opportunity for the earlier identification of children with special difficulties which, if neglected, may inhibit their educational progress. These difficulties may be predominantly social, psychological or medical. It will be important to ensure that such children's parents are made aware of the facilities available; remedial measures are much more likely to be effective if applied early. Close contact between those responsible for the education of the children and social workers, educational psychologists, nurses and doctors will be of great importance.
>
> In preparing for the expansion of nursery education, local authorities will need to take account of other facilities for under fives, existing or planned, so as to prepare a scheme for their areas in which nursery classes and schools, voluntary playgroups, day nurseries and other forms of day-care all play their part. The Government attach importance to a full assessment of local resources and needs, and will welcome diversity in provision so long as it is efficient and there is no sacrifice of standards in the education and care of the children. The main burden of this responsibility must rest on education departments, but other departments of local authorities will need to share in it, and consultation with voluntary bodies will also be necessary in many areas.
>
> The Government believe it would be right for most of the extra nursery provision to take the form of classes for the under fives forming part of primary schools. Educationally this has the advantage of avoiding a change of school at five. It is important that the classes—new and existing—should be housed, staffed and equipped to meet the special needs of young children. Where standards in existing classes wholly or mainly for children under five are below those appropriate for nursery classes, additional assistance to teachers and improvements in equipment, accommodation and outdoor playing space may be required.

The White Paper, the first major statement of policy since the Butler Act of 1944, also emphasised the importance of voluntary effort and of the rôle of parents. It said:

> Authorities should consider carefully the rôle of voluntary playgroups. Many thousands of mothers devote considerable time and energy to running and organising such groups, which make an important contribution, providing for over a quarter of a million children under five. The Government have substantially increased their financial support for the playgroup movement. They hope that the development of playgroups will continue, particularly among socially deprived children, and that local authorities will consider how the best use can be made of them. Some playgroups, if provided with better equipment and qualified staff, could become maintained nursery classes: part of the primary school but on a separate site. Playgroups will continue to have a distinct and valuable rôle to play alongside an expanding system of nursery education. These voluntary groups may be assisted by local authorities in their various capacities by cash grants, the loan of equipment, or the advice

of the authority's nursery and infant specialists. They may be associated with a local primary school, and so enjoy the support of qualified teachers. Where playgroups are supported in this way, it will be important to ensure that they provide the same opportunities as in maintained schools for identifying children with special handicaps.

Local education authorities will also wish to adapt and apply to nursery education lessons which can be learnt from the experience of playgroups. The most successful of these have derived much strength from the support of parents, which the playgroup can generate by providing a focus of interest in education in a community. Some mothers have been able to give practical help in running playgroups; as nursery education expands, many more may wish to have some training, such as a further education college can provide, in order to make the most of their time and their skills whether working in a playgroup or a nursery class. Their maturity and experience with children are important assets. In addition, nursery education probably offers the best opportunities for enlisting parents' understanding and support for what schools are trying to achieve, which is of key importance to successful education at subsequent stages.

Nursery schools are in the charge of specially qualified teachers, and with one teacher and an assistant for every 20 children, their classes are smaller than those in primary schools with 30 children. Usually, there are no formal lessons and the children sing, and dance, or listen to stories or play with water, sand, clay, boxes, old car tyres, and climbing frames, as well as learning to realise the values of money, weights, and measures by playing at shops and practising domestic chores. It is a period of attitude and habit formation, with as much attention paid to social behaviour and physical health as to preparation for more academic learning. A lot of trouble is taken to introduce children to school carefully, although methods vary, with some teachers believing in gradual weaning, and others preferring children to attend alone.

Primary Education.

More than half of the 23,000 primary schools cater for juniors and infants. About a quarter are for infants only (5–7), and most of the rest are for juniors only. The great majority are mixed and only the largest cater for so many as 300 pupils. The great majority have fewer than 200. Fewer than 200,000 of primary school children are in " oversize " classes (more than 40 children per teacher). The average number of pupils per teacher in 1969 was 28 and the average size of class was 33, but the aim of improving the supply of teachers enabling smaller classes, is being achieved. Transfer to secondary schools is usually at 11. In the predominantly Welsh-speaking areas of Wales, the main language of instruction is Welsh. There are bilingual schools in mainly English-speaking parts of Wales.

Over the past decade, there has been a revolution in methods of teaching in primary schools, so much so that they are the envy of the world. There has also been controversy about the " new " primary schools, aroused by a view that the children seem to be playing instead of working. Such methods, based on the argument that children learn by " finding out " instead of " being told," by discovery instead of drill, is not, in fact, so new as it seems. A report on primary schools, published by the Board of Education in 1931, said:

> . . . At the age when they attend the primary schools, children are active and inquisitive, delighting in movement, in small tasks that they can perform with deftness and skill, and in the sense of visible and tangible accomplishment which such tasks offer; intensely interested in the character and purpose—the shape, form, colour and use—of the material objects around them; at once absorbed in creating their own miniature world of imagination and emotion, and keen observers who take pleasure in reproducing their observations by speech and dramatic action; and still engaged in mastering a difficult and unfamiliar language . . . These activities are not aimless, but form the process by which children grow.

The report concluded that the school curriculum should therefore be thought of in terms of activity and experience rather than of knowledge to be acquired and facts to be stored.

Some 25 years later, in 1967, a report from the Central Advisory Council for Education under Lady Plowden surveyed British primary education and concluded that discovery methods were successful. The Plowden report has proved to be one of the major educational documents of the past 25 years and its considered views are worth noting. " Finding out, " it said, had proved to be better for children than " being told. "

It added:

> Children's capacity to create in words, pictorially and through many other forms of expression, is astonishing. The third of the three R's is no longer mere mechanical arithmetic, French has made its way into the primary school, nature study is becoming science. There has been dramatic and continuing advance in standards of reading. The gloomy forebodings of the decline of knowledge which would follow progressive methods have been discredited. Our review is a report of progress and a spur to more.
>
> This may sound complacent. We are not. The more dismal corners of primary education produce plenty of evidence of parochialism, lack of understanding of the needs of children and of the differing homes from which they come, lack of continued training of teachers and lack of opportunities for professional contact. Had we ignored these facts, we should have ignored what is well known to teachers and, increasingly, to parents. If all or most teachers are to approach the standards of the best, far more effort must be put into their in-service training.
>
> There may be a good school without good buildings, though this is no excuse for the deplorable conditions in which many children are educated. There cannot be a good school without good teachers. Even one or two can leaven a whole staff. But there are staffs without leaven. We set these facts down here lest we should be accused of wilful ignorance because in the Report we have for the most part described English primary education at its best. That in our belief is very good indeed. Only rarely is it very bad. The average is good.

Another major theme of the Plowden Report was its emphasis on the rôle of parents in children's educational development and the importance of improving relationships between schools and homes. Its research, it said, suggested that the most vital factor in a child's home was the attitude to school, and all that went on there, of its mother and father: " The interested parent has the interested child. "

All this explains why the primary schools of the 1970s are so very different from those even of the 1950s, with open-plan classrooms and children engaged in an often bewildering variety of activities, which may seem at first sight to have nothing to do with learning. Yet the good teacher exploits each activity for an educational purpose. Schools are now happier places and the evidence is that academic standards have been maintained and even improved.

Secondary Education.

Secondary education usually starts at 11, although there are a growing number of " middle schools, " spanning both primary and secondary schools and catering for children of 8–12, 9–13, or 10–13. So much change has occurred in the past decade that there is no single pattern of secondary schooling which applies throughout the country, and schools in many areas still remain in a state of flux.

About half of secondary schools have between 300 to 600 pupils but the largest have as many as

2,000. Children in some areas are selected for different types of schools—comprehensive, grammar, or modern—by their level of attainment (often still assessed by means of the 11-plus examination, a test of English, arithmetic, and verbal reasoning). Grammar schools give a mainly academic course for selected pupils from 11 to 18. Secondary modern schools provide a general education until the minimum school-leaving age of 16, although many pupils stay on beyond 16. There are also a few technical schools, specialising in technical studies, and various combinations of grammar, technical, and modern schools.

About 41 per cent of State secondary school pupils in 1972 were in comprehensive schools. Six forms of comprehensive school were described by the Government in 1965:

—The orthodox comprehensive school with an age range of 11–18—the " all-through " school.
—A two-tier system where all pupils transfer at 11 to a junior school and all go on at 13 or 14 to a senior school.
—A two-tier system where all pupils transfer to a junior comprehensive at 11, some transfer to a senior comprehensive at 13 or 14, and the rest remain in the junior.
—A two-tier system in which all pupils transfer to a junior school at 11 and at 13 or 14 are given the choice of a senior school to 18 or another to 16.
—Comprehensive schools with an 11–16 age range, combined with sixth form colleges.
—A three-tier system, with transfer occurring at 8 or 9 and at 12 or 13.

Special Schools

Special educational treatment is provided for children handicapped by a disability of body or mind and it is the duty of each local education authority to provide for pupils who are blind, partially sighted, deaf, partially hearing, delicate (including diabetic), educationally sub-normal, epileptic, maladjusted, physically handicapped, and speech defective.

Special educational treatment can also be given in ordinary schools, special classes, boarding homes and hostels, hospitals, clinics, or in children's or teachers' own homes. Education authorities may also pay for the education and maintenance of handicapped pupils in independent schools recognised as suitable by the Department of Education and Science (DES).

According to the Government, the particular function of special schools is to provide a regime to overcome the learning difficulties of handicapped children and to educate them to become so far as possible self-reliant and responsible adults.

> To this end the schools have a more generous staffing ratio and provide physiotherapy, speech therapy and other forms of treatment as well as special teaching facilities. About three-quarters of the maintained special schools are day schools. For children with severe handicaps, for whom day special schools cannot cater, and for children who live out of reach of a suitable day school, free boarding education is provided. Attendance at school is compulsory from five to sixteen, but pupils for whom a further period of education in the special school would be beneficial are able to stay longer. In addition to the provision in special schools, a small proportion of handicapped children are being educated by the authorities in their own homes or in small groups. A few special establishments provide physically handicapped or blind school leavers with a period of further education, pre-vocational training and assessment for employment. (Subsequent vocational training is the responsibility of the Department of Employment.) Some handicapped pupils attend ordinary establishments of further and higher education.

Independent or Direct Grant Schools.

There are 176 direct grant schools in England and Wales, 94 for girls, 80 for boys, and 2 mixed, almost all of which are ancient grammar schools, many with boarding departments, and occupying a mostly independent position but also getting significant support from the State.

Such schools are independent of their local education authority, but are required, in return for their direct grant from the Government, to make at least a quarter of their places available free to pupils from State primary schools, as well as admitting children whose fees are paid in part (on a means test) or wholly by parents. Since they can take the most gifted children, direct grant schools regularly top the list of schools gaining awards at Oxford and Cambridge. The second report of the Public Schools Commission showed that their pupils do proportionately better than those at State or public schools at GCE " A " level and university entry.

Public Schools.

A public school is defined by being in membership of the Headmasters' Conference (about 200), the Governing Bodies Association (130, including 65 direct grant schools), or the Governing Bodies of Girls' Public Schools (about 140 independent and some 60 direct grant schools).

Their pupils comprise 2 per cent of the age group, but some 20 per cent of those at universities and they hold two in three of the top jobs in the professions. The typical English public school is a mid-19th cent. Church of England foundation, in a small country town. The school is unendowed and the fees will vary between £500 to £900. Entry is normally at 13 instead of 11, the staffing ratios are more favourable—about 11:1—and it is usually a boarding school. There is also a conscious aim to develop qualities of character and leadership as well as Christian qualities, but the curriculum is no different from that of a State grammar school.

Other Independent Schools.

There are nearly 2,000 other independent schools which charge fees. All have to be officially registered with the Department of Education and Science and open to inspection. About half are also " recognised as efficient, " which means that they reach the standard of provision and level of efficiency that the Government demands of State schools.

Preparatory Schools.

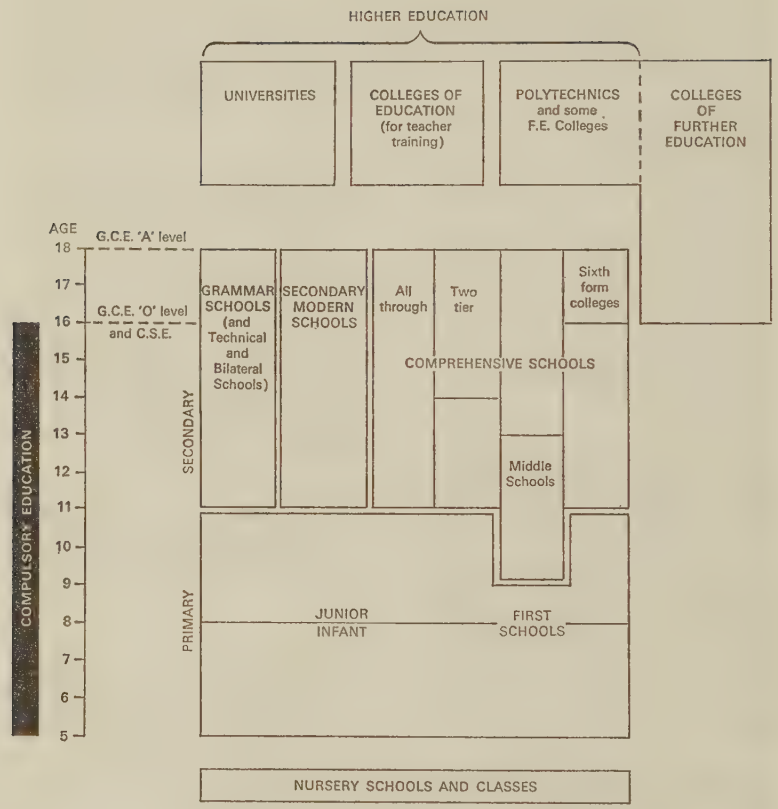
Prep schools, as they are known, prepare boys—and now a few girls, for entry to independent schools. Most are privately owned and the great majority are boarding schools, accepting pupils from the ages of 8 and 9. About 500, with some 60,000 pupils, are in membership of the Incorporated Association of Preparatory Schools, which is in close relationship with the HMC, and also oversees standards. The Common Entrance Examination, required for entry to public schools is taken between 12 and 14.

II. FURTHER AND HIGHER EDUCATION

It is easy to get confused in defining what constitutes " further " as opposed to " higher " education, but the most useful definition of higher education is that it is full or part-time study in universities, polytechnics, colleges of education, and some other major colleges leading to qualifications beyond the GCE " A " level or the Ordinary National Certificate—the Higher National Diploma, the new Diploma of Higher Education, or degrees of universities and the Council for National Academic Awards. Further education comprises all other education beyond the age of 16, carried on in colleges.

Further Education.

The hallmark of further education is diversity and variety and more than three million students are enrolled for courses which are offered in vocational and academic subjects from craft to professional level and from GCE " O " level to first and higher degrees. There is also provision for cultural and leisure activities. Among the 600 to 700 main institutions are technical colleges, colleges of commerce, colleges of art, agricultural colleges, and evening institutes, as well as the new



polytechnics. Study may be full-time, sandwich (where periods of study alternate with practical training in industry), or part-time during the day or evening. There are no formal entry requirements, a student can take a course at the level appropriate for him and the colleges put on any courses for which there is a demand.

Courses often reflect the interests of local industry and commerce. Since 1964, industrial training boards have been established and more young workers are now being released by their employers to attend further education courses, either for a day a week, coupled with evening study, or short periods of full-time study. Such courses often lead to recognised qualifications such as the certificates of the City and Guilds of London Institute, the Royal Society of Arts and the regional examining bodies, and the ordinary and higher national certificates, awarded by the professional associations and the DES. The entry qualification for the Ordinary National Certificate is four passes at GCE " O " level, or by general engineering courses starting at 16. After the ONC, a student can go on to the Higher National Certificate or Diploma and then to membership of a professional institution—or to degrees.

Higher Education.

Universities.

The universities are independent institutions, established by Royal Charter, devoted to teaching and research. All are national and open to students from any part of Britain. The minimum entry qualifications are usually two GCE " A " level passes and five " O " levels or 3 " A " levels with four " O " level passes. Since competition for entry, especially in arts and social sciences subjects, is fierce, universities usually stipulate further requirements described in terms of " A " level grades. A student wanting to read history, for example, might be asked for three " A " level passes, at grades of, say, two Bs and a C, or one A and two Bs.

Entry is co-ordinated by the Universities Central Council on Admissions. Applicants are allowed to make five choices of university. Applications are then sent to the universities, which may invite candidates for interviews, make conditional or unconditional offers without interview, or reject them. A clearing house is organised in September for candidates still seeking a place in October.

The universities are: Aberdeen, Aston in Birmingham, Bath, Belfast, Birmingham, Bradford, Bristol, Brunel, Cambridge, City, Dundee, Durham, East Anglia, Edinburgh, Essex, Exeter, Glasgow, Heriot-Watt, Hull, Keele, Kent at Canterbury, Lancaster, Leeds, Leicester, Liverpool, London (comprising Bedford, Birkbeck, Chelsea, Imperial, King's, London School of Economics, Queen Elizabeth, Queen Mary, Royal Holloway, School of Oriental and African Studies, University College, Westfield, Wye, Courtauld Institute of Art, Institute of Archaeology, School of Slavonic and E. European Studies), Loughborough, Manchester, Manchester Institute of Science and Technology, Newcastle upon Tyne, Nottingham, Oxford, Reading, St. Andrews, Salford, Sheffield, Southampton, Stirling, Strathclyde, Surrey, Sussex, Ulster, Wales (at Aberystwyth, Bangor, Cardiff, Swansea, Lampeter), University of Wales Institute of Science and Technology, Warwick, York.

The first degree course usually lasts for three years and is taught by means of lectures, tutorials, seminars, and the student's own reading. Courses are divided almost equally between those based on the arts and those based in the sciences. About 17 to 18 per cent of graduates, including many from overseas, go on to postgraduate courses to read for a master's degree or a doctorate. Maintenance grants are made to students on a means-tested basis (and to students in polytechnics and colleges of education).

Other institutions where the work is of university standard are the Manchester Business School, the Royal College of Art, the London Graduate School of Business Studies, and Cranfield Institute of Technology.

The Polytechnics.

All 30 polytechnics have now been designated and it is the aim of the Government that they should become major institutions of higher education. There will be as many students in polytechnics and colleges of education by 1981 as in universities.

The polytechnics are: Birmingham, Brighton, Bristol, Glamorgan, Hatfield, Huddersfield, Kingston, Lanchester, Leeds, Leicester, Liverpool, Central London, City of London, North London, North East London, South Bank (London), Thames, Manchester, Middlesex, Newcastle-upon-Tyne, North Staffordshire, Oxford, Plymouth, Portsmouth, Harris in Preston, Sheffield, Sunderland, Teesside, Trent, Wolverhampton.

The intention is that they should be comprehensive institutions, dealing mainly in higher education but also in further education, devoted mainly to teaching and not to research, catering for full-time, sandwich course, and part-time students, and forming strong links with their local communities. They are not independent like the universities but administered by local education authorities under strong direction from the Department of Education and Science.

The philosophy which led to their creation was outlined by Mr. Crosland, as the then Secretary of State for Education and Science, in 1967:

> There are two categories of students whose importance to the nation can hardly be overestimated. First, there are the tens of thousands of students who want to do a full-time course which, although not of degree standard, leads to one or other of the many professional qualifications marked by a certificate or an associateship. Secondly, there is the huge and growing army of part-time students at all levels, almost all of them already in employment. Now the universities cannot cater for these without a complete transformation of the university system of a kind which would not be practicable for many years ahead and which in any case neither Robbins nor anyone else has recommended. We must therefore cater for them in the technical colleges and in the future Polytechnics.
>
> But is it not then highly desirable that these colleges should also embrace a third category of full-time degree students? First, there are strong educational arguments for this. I believe that there will be great educational advantage from the existence alongside the universities of more broadly based higher education institutions in which full-time, sandwich and part-time students at all levels of higher education work together. In academic as well as human terms there is no hard and fast line between the different categories. Each will have much to gain and much to give and all will benefit from belonging to the same academic community.
>
> Secondly, the inclusion of full-time degree work carries on the historic and invaluable FE tradition of providing opportunities for educational and social mobility. The colleges have always catered amongst others for the students who cannot on entry show that they are of university calibre, and for those who can profit from a university course but cannot give their whole time to it. Technical college teachers could quote hundreds of examples of students in these categories who have been helped by good teaching and their own strong motivation subsequently to tackle a full-time degree course. Perhaps they left school early, perhaps they were late developers, perhaps they were first generation aspirants to higher education who were too modest at the right moment to apply to a university, perhaps they had started on a career and thought that a technical college course would more directly improve their qualifications for doing it. The important thing is that the leading technical colleges, by their capacity to provide for students at different levels of ability and attainment (and that is why I call them comprehensive), provide a chance for students of these kinds not only to tackle degree level work part-time or full-time, but also to develop their latent capacity to do so. This range of opportunity is a precious part of our educational heritage that we would be mad to abandon. No wonder some other countries envy what has come to be called the open-ended rôle of the technical colleges—the rôle of providing the second chance the alternative route.
>
> Thirdly, the inclusion of full-time degree work is the best way of avoiding a most undesirable social and educational division at eighteen.

Students usually work for degrees of the Council for National Academic Awards, whose qualifications are accepted as the full equivalent of universities' degrees for instance for the purposes of professional recognition, student awards and by the professional institutions. CNAA courses are normally oriented more to the application of knowledge and have a strong vocational emphasis. Many are sandwich courses, for instance. Polytechnics design their own courses, like the universities, and set and mark the examinations, but there are external examiners (again as in the universities) to ensure an equivalence of standards.

Colleges of Education.

There are more than 160 colleges of education, almost wholly devoted to the training of teachers, which lasts for three years and gives qualified teacher status, with the possibility of a fourth year to read for a Bachelor of Education degree. (There are a few departments of education in polytechnics and 29 in universities which offer one year postgraduate courses of teacher training.) Most of the colleges are small—the largest having about 1200 students—but offer residential facilities for the majority of students.

Now that the problem of teacher supply is not so acute, the Government plans big changes for the colleges, which will bring some of them into the mainstream of higher education and diminish their function as simply trainers of teachers. Its White Paper of 1972 said:

The quality of experience of their staff and the strength of their physical resources admirably equip a number of the colleges to share in the expansion of higher education. The Government intend that, subject to what was said in paragraph 145, some colleges either singly or jointly should develop over the period into major institutions of higher education concentrating on the arts and human sciences, with particular reference to their application in teaching and other professions. Others will be encouraged to combine forces with neighbouring polytechnics or other colleges of further education to fill a somewhat similar rôle.

Many of the 160 colleges are, however, comparatively small and inconveniently located for development into larger general purpose institutions. Some of these will continue to be needed exclusively for purposes of teacher education with increasing emphasis on in-service rather than initial training. Some may seek greater strength by reciprocal arrangements with the Open University on the lines of the experiment recently initiated. Others may find a place in the expansion of teachers' and professional centres. Some must face the possibility that in due course they will have to be converted to new purposes; some may need to close.

Many of the colleges, therefore, will become fully-fledged institutions of higher education, offering a wide variety of courses with no initial commitment to teach involved on the part of the student. Some have already formed academic links with the Council for National Academic Awards; others—and the situation will be fluid until 1976 or 1977—will remain with the universities. The most up-to-date information can be obtained from the colleges' Central Register (*see* R12).

Over the past decade, the number of students in universities, polytechnics and colleges of education has doubled; according to one commentator higher education was the biggest growth industry in the sixties apart from electronics and natural gas. The rate of expansion in the seventies will be equally spectacular.

In its White Paper, the Government ventured to offer some of its own thoughts on the purposes of higher education, which will obviously influence developments in the seventies. The crucial section, devoted to the theme " After School and Beyond " said:

> The motives that impel sixth formers to seek higher education are many, various and seldom clear-cut. A minority wish to continue for its own sake the study in depth of a specialised subject to the top of their bent. It is crucial for the world of scholarship, research and invention that their needs should be met. This has always been a leading function of the universities and must remain so. Some students have a specific career in mind. A larger number are anxious to develop over a wider field what the Robbins Committee called the general powers of the mind, but not without questioning whether a specialised honours degree course is the best way of achieving it. Some ask for no more than a stimulating opportunity to come to terms with themselves, and to discover where their real interests and abilities lie. Others have no better reason than involuntarily to fall in with the advice of their teachers and the example of their contemporaries. But not far from the surface of most candidates' minds is the tacit belief that higher education will go far to guarantee them a better job. All expect it to prepare them to cope more successfully with the problems that will confront them in their personal, social and working lives.
>
> It is important that the last and most widespread of these expectations should not be disappointed. The Government have sympathy with the sincere desire on the part of a growing number of students to be given more help in acquiring—and discovering how to apply—knowledge and skills related more directly to the decisions that will face them in their careers and in the world of personal and social action. This is what is meant by " relevance ". The wider the span of student motivation, the greater the need to match it with a wide and flexible choice of course. This is being achieved increasingly by a system of units and credits devised in such a way as to ease transfer from one course or institution to another—which should help students to retrieve false starts and make more possible the development of recurrent education.

One new development resulting from the White Paper will be the introduction of a new two-year qualification, the Diploma of Higher Education, which will be both a terminal qualification or credit towards a degree or professional qualifications. Students reading for diplomas will get mandatory maintenance grants.

The Open University.

Often described as the university of the second chance, the Open University started in 1971 and now has a world-wide reputation. (Mr Harold Wilson outlined the Labour Party's proposal for a " University of the Air " (as it was originally called) in 1963 and on attaining office the next year Miss Jennie Lee was appointed Minister responsible for carrying the project into effect.) It provides courses for adults over 21, who did not enter conventional institutions of higher education at 18, and is now the largest British university. No formal entry qualifications are required and degrees are taken part-time by BBC television and radio, correspondence courses and tutorials. The university has 250 study centres and puts on short residential courses. There is also a national network of student counsellors. One estimate is that it takes ten hours a week to gain the credits for a degree over a minimum of four years. Information about the university can be obtained from the Open University, P.O. Box 48, Bletchley, Bucks.

III. SOME CONTROVERSIAL ISSUES.

Since education is so crucial in the cultivation of a nation's cultural life and the attitudes and habits of its citizens, it inevitably arouses controversy and this section discusses some of the issues that have been debated by parents and educators in the past few years.

Children's Growth and Development.

The Plowden report summarises the present state of knowledge. One major point, underlining the new concern for nursery education, is that children are growing faster at birth than at any other age. After 6, the rate is nearly constant until puberty, at any time from 11 to 14, starting earlier in girls, when another spurt occurs. From early foetal life onwards, the gross weight of the brain is nearer to its adult size than any other organ—25 per cent of its adult weight at birth, 50 per cent at six months, and 90 per cent at five years, when a child has reached only 40 per cent of its adult stature. The implications of the present knowledge about the development of children, according to the Plowden report, were:

> (*a*) Individual differences between children of the same age are so great that any class, however homogeneous it seems, must always be treated as a body of children needing individual and different attention.
>
> (*b*) Until a child is ready to take a particular step forward, it is a waste of time to try to teach him to take it.
>
> (*c*) Even at the ages with which we are concerned, boys and girls develop at different rates and react in different ways—a fact which needs particular attention because we have co-educational schools. Boys are more vulnerable to adverse environmental circumstances than girls. Both reach maturity earlier than they did.
>
> (*d*) Though I.Q. scores are a useful rough indication of potential ability, they should not be treated as infallible predictors. Judgments which determine careers should be deferred as long as possible.

(e) Since a child grows up intellectually, emotionally, and physically at different rates, his teachers need to know and take account of his "developmental age" in all three respects. The child's physique, personality, and capacity to learn develop as a result of continuous interaction between his environmental and genetical inheritance. Unlike the genetic factors, the environmental factors are, or ought to be, largely within our control.

Streaming and Family Grouping.

Streaming involves the allocation of children in separate classes on the basis of their academic ability, so that a school with four classes in each year may describe them as 3A, 3B, 3C, and 3D. Supporters of streaming say that children learn better and that it is easier to teach them in homogeneous groups, where all are of roughly the same ability.

Opponents, now including many parents, make several criticisms of streaming. One is that streaming usually begins too early, at the age of 7 and that it effectively condemns the rejected children in B, C, and D streams, since they conform to their teachers' expectations of them. Another argument is that streaming tends to select children by class and that children should not be segregated from other, different children throughout their school lives. Many schools are now experimenting with mixed ability groups. A report by the National Foundation for Educational Research found that unstreamed classes made no difference to academic attainment, nor to hobbies, nor to the all-round advantages of above-average children. It was of benefit to average and below-average children in several aspects of their social and mental life but only partly counteracted the disadvantages of a semi-skilled or unskilled social background.

One new form of organisation is family grouping, in which children of different ages, say 5, 6, and 7, are in the same class. Older children help younger children, while children who are good at reading help those who are not—as in the family situation.

Caning.

Corporal punishment is still a feature of British schools and surveys show that the overwhelming majority of teachers oppose its abolition. The legal position is that a teacher, who stands in the position of a parent within the school, is held to be justified in using a reasonable amount of force by way of correction. Magistrates convict teachers when they judge that an unreasonable amount of force has been used. Elsewhere, corporal punishment has been almost universally outlawed. The Plowden report recommended in 1967 that the infliction of physical pain as a method of punishment should not be allowed but no action has yet been taken.

Standards of Reading.

A recent report by the National Foundation for Educational Research found that the consistent improvement of junior children's standards of reading had stopped but was nevertheless still at the same level as in 1960.

Average scores on the Watts–Vernon test of 11-year-olds were 11·59 in 1948, 12·42 in 1952, 13·30 in 1956, 15·00, in 1964, and 14·19 in 1970. In 1964, 11-year-olds matched the standard of pupils of 12 years 5 months in 1948. Among seniors, scores were 20·79 in 1948, 21·25 in 1952, 21·71 in 1956, 24·1 in 1961, and 23·46 in 1971. Standards improved by nearly 20 months' reading age between 1948 and 1961.

Selection.

Children are selected for grammar schools by means of the 11-plus examination, consisting of tests of intelligence, tests of attainment in English and arithmetic, school records and teachers' recommendations, and, in borderline cases, interviews. (Many education authorities are now turning to a "profile" of children, based on their regular school work, instead of one isolated examination.) Intelligence tests produce a rating called the intelligence quotient, or the IQ, which represents a child's mental age, measured by the tests, expressed as a percentage of chronological age. A child of ten whose mental age is 12 has an IQ of 120. A child of 10 whose mental age is 8 has an IQ of 80. Children with IQs of 120 and over usually qualify for grammar schools, although the proportion of children admitted varies from county to county, at its extreme from 10 to 40 per cent. Comprehensive schools do away with the need for the 11-plus but secondary schools still need guidance on the attainment of the children they receive from primary schools. A recent report showed that 64 per cent of 11-year-olds are still selected for secondary education, although 50 areas do not operate any selection procedure. Out of every 20 children selected for grammar schools by the 11-plus, it has been shown that six or seven are academically unsuited to them and that they keep out another six or seven of the remaining 80 sent to secondary modern schools who should have been admitted. Such evidence led to the campaign to end selection at 11. *See also* Q28.

IV. GENERAL INFORMATION.

School Examinations.

The main examination for schools is the General Certificate of Education, which can be taken at Ordinary and Advanced (and also Scholarship) levels, usually at 16 and 18 respectively, or in the fifth and second year sixth forms. There are eight examining boards, all but two of them university boards: Associated Examining Board, University of Cambridge Local Examinations Syndicate, Northern Universities' Joint Matriculation Board (the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham), University of London University Entrance and School Examinations Council, Oxford and Cambridge Schools Examination Board, Oxford Delegacy of Local Examinations, Southern Universities' Joint Board for School Examinations (Universities of Bristol, Exeter, Reading, and Southampton), Welsh Joint Education Committee.

The papers vary from board to board, but standards are accepted as comparable by universities and professional bodies. Each board devises its own syllabuses, sets its own questions and publishes the results. Most pupils sit from 5 to 10 Ordinary level papers and two or three at Advanced level, where passes are given in the grades of A, B, C, D, and E and get a certificate recording their successes. Some 50 different papers can be sat at O level and about 40 at A level. About 500,000 pupils sit the GCE each year.

A new examination, the Certificate of Secondary Education (CSE) was introduced in 1965. It is also a nationally-recognised qualification, but unlike the GCE is substantially organised by teachers, who are in the majority on all its administering bodies. There are three "modes" of the CSE. Schools can submit candidates for the regional examining boards' examinations, or put up their own schemes, or, in Mode 3, set their own papers and mark them internally, under the moderation of the examining boards. It is a subject examination but includes non-academic subjects, such as typewriting or building and engineering science. Candidates do not pass or fail: they are either given one of five grades or are not graded at all. Grade 1 is considered as comparable to a GCE "O" level pass, while Grade 4 suggests a standard expected of a 16-year-old of average ability.

The CSE is intended for candidates whose ability overlaps that of pupils sitting GCE "O" level. Some 20 per cent of pupils are considered capable of the GCE and the next 40 per cent of the CSE.

Religious Education.

Section 25 of the 1944 Education Act says that the school day in every state school shall begin with collective worship and religious instruction shall be given in every school. Children can, however, be excused both the act of worship and religious instruction if their parents wish. Religious instruction in church schools is denominational and controlled by the managers and governors. The syllabus in state schools is agreed

between the local education authority, the religious denominations and teachers' associations. Denominational religious instruction in church schools may be given in not more than two periods a week to those children whose parents ask for it.

School Curricula.

Schools in Britain are perhaps unique in the freedom allowed to teachers to teach as they see fit, with no guidelines laid down by the Government. Inside his classroom, the teacher has absolute freedom. Headteachers, subject to managers or governors, are equally free to organise their schools according to their own philosophies: to insist, for instance, on streaming or non-streaming policies.

Special Services.

All schools offer a cheap midday meal which are taken by about 70 per cent of children, while milk is free in infant schools and sold to pupils in primary and secondary schools. Local education authorities have the power to provide children with clothing and to see that they are not verminous. Orders for the cleansing of children can be made. Medical and dental treatment is provided for all schools.

The Major Reports.

There have been four major reports since 1958 dealing with the mainstream of education.

The **Crowther Report** in 1958 dealt with the education of boys and girls aged 15–18. It was the first report to show how significantly social background determined whether children left school at 15. Its main recommendation was that the school-leaving age should be raised to 16 (achieved, finally, in 1972–73).

The **Newsom Report** in 1963 considered the education between 13 and 16 of pupils of average or less than average ability (basically, the secondary modern schools). It supported the main Crowther proposal, as well as its suggestion that many children were held back more by social than genetic factors, and showed that standards were rising but that four out of five secondary modern schools were seriously deficient. It appealed for a change of heart for the children who were "half our future."

The main principle of the **Robbins Report** on Higher Education was that all students who were qualified by ability and attainment to go to university or college should be able to do so. It recommended a massive expansion of higher education which not only occurred but exceeded the targets set in the report.

The last was the **Plowden Report** (already discussed in some detail). Perhaps the most significant of its proposals was that special extra help should be given by the Government to schools in deprived social neighbourhoods—that there should be "positive discrimination" in favour of the disadvantaged—which was accepted by the Government.

V. ADMINISTRATION AND GOVERNMENT OF EDUCATION

The Government.

The duty of the Secretary of State for Education and Science is to promote the education of the people of England and Wales and the progressive development of institutions devoted to that purpose, and to secure the effective execution by local authorities, under his control and direction, of the national policy for providing a varied and comprehensive educational service in every area.

The Secretary of State for Education and Science is a member of the Government of the day, and is assisted by two Parliamentary Under-Secretaries of State. The Department of Education and Science, of which the Secretary of State is the political head, is staffed by civil servants, whose appointments are not dependent on political considerations.

The central government does not run any schools or colleges, or engage any teachers, or prescribe any textbooks or curricula, but it does set minimum standards of educational provision; control the rate, distribution, nature, and cost of educational building; control the training, supply, and distribution of teachers; and determine the principles governing recognition of teachers as qualified; administer a superannuation scheme for teachers; in consultation with local authority associations, forecast the level of local authority expenditure on education to be taken into account in determining the size of the Exchequer grant (*i.e.*, the Rate Support Grant); support financially by direct grant a limited number of institutions of a special kind; support educational research through the agency of the National Foundation for Educational Research, university departments, and other bodies; settle disputes, for example between a parent and a local education authority, or between a local education authority and the managers of a school.

The Secretary of State for Wales is also a member of the Government. He is responsible for all schools in Wales, including nursery, primary and secondary schools, special schools, direct grant and independent schools. The Welsh Education Office in Cardiff, which is part of the Welsh Office, is staffed by civil servants and operates similarly to the Department of Education and Science.

The Secretary of State for Education and Science is responsible for all other educational functions in Wales and has staff in London and also in Cardiff, all of whom form part of the Welsh Education Office, but are on the staff of the Department of Education and Science.

Her Majesty's Inspectorate reports to the Secretary of State on education in schools and in colleges. All schools of whatever kind are open to inspection. Inspectors also offer advice to local education authorities, colleges, and schools and discuss day-to-day problems with them. The Inspectorate gives professional educational advice to the Department, provides a focus for educational developments, conducts courses for serving teachers, and prepares advisory publications, as the Government puts it.

There are about 500 HM Inspectors of Schools in England under a senior chief inspector. There are six chief inspectors, three concerned mainly with the work of the schools, two concerned with further education, and one concerned with the training of teachers. Some 60 staff inspectors are responsible on a national basis for particular subjects, for example English, modern languages, engineering, art, or for particular sectors of education, secondary education, or the training of teachers. The country is divided into nine divisions, each with a divisional inspector. The Inspectorate in Wales (nearly 50) is organised on similar lines under the Chief Inspector for Wales.

Local Education Authorities.

Local education authorities are responsible for providing education, other than in universities. They are the elected councils of towns and counties. Officers of the authority are responsible to the Education Committee. Education authorities build schools, employ teachers, local inspectors of schools and education organisers, and provide equipment and materials. It is their duty to secure that there is efficient education at all levels to meet the needs of the local population. What is taught is normally decided on their behalf by the headteachers of schools.

Education is the largest of the services provided by local authorities and the cost is met from rates (a local property tax) and from Rate Support Grant payable from the national Exchequer by the Secretary of State for the Environment. The grant is in aid of all the services provided by the local authorities with the exception of housing and trading services. In 1972–73 it was estimated that the total of exchequer assistance to local authorities would amount nationally to 58 per cent of their expenditure on the relevant services.

Local government outside Greater London was reorganised on 1 April 1974 (*see* **Section C, Part II**). The reorganised system is based on two forms of operational authorities, each being responsible for a different set of functions. Wales is reorganised into 8 new counties and 37 new districts. The new counties are responsible for education.

In England, there are 45 new counties each of which is divided into districts. Outside 6 of the most populated of these counties, responsibility for education, as in Wales, falls to the new counties. But in the six "metropolitan" areas the division of function between the counties and the districts falls on a different basis and responsibility for education is allocated to the 34 districts.

The overall effect is to reduce the present number of local education authorities from 146 in England and 17 in Wales to a total of 101. The 101 comprise 38 new counties and the 34 new "metropolitan" districts in England, the 8 new counties in Wales, the 20 existing outer London boroughs, and the Inner London Education Authority.

School Administration.

State primary schools have a body of managers and secondary schools a body of governors, who are responsible, in consultation with the head-teacher, for the general direction of conduct and the curriculum, although the head has effective control over organisation and discipline.

State schools are either county schools or voluntary schools, and this affects the details of their government. County schools are established by the local education authority, voluntary schools by other bodies, mainly the churches.

The managers or governors of county schools are appointed by the local authorities (or the power to do so may be delegated to the Excepted Districts and Divisional Executives). The voluntary schools are of three kinds: controlled, aided, and special agreement. In controlled schools two-thirds of the managers or governors are nominated by the authority, the remainder by the voluntary interest; all costs are borne by the local authority, which appoints the teachers. At an aided school the voluntary body appoints two-thirds of the managers or governors, who are responsible for repairs to the exterior of the school building and make all improvements, enlargements, or alterations to it. The State makes grants of up to four-fifths of their approved capital expenditure including (since 1967) the cost of projects providing new schools or those enlargements of existing schools not formerly eligible for grant. The authority pays for maintenance, pays the teachers, and meets running costs. The appointment of teachers is controlled by the managers or governors. Special agreement schools are those where authorities have, by special agreement, paid between one-half and three-quarters of the cost of building a new, or extending an existing, voluntary school, almost always a secondary school. Two-thirds of the governors are appointed by the voluntary body. Expenditure is normally apportioned between the authority and the voluntary body as in an aided school.

A useful guide to educational terms is contained in *A Guide to English Schools* (Tyrrell Burgess, Pelican).

MODERN GARDENING

A guide for the gardener on all aspects of modern horticulture particularly in the control of pests and diseases and the eradication of weeds by the latest means.

TABLE OF CONTENTS

Cultivation of Flowers	3–15
Making a Lawn	15
Cultivation of Fruit	15–18
Cultivation of Vegetables	19–26
Fertilisers and Organic Manures	26–28
Garden Pests	28–30
Diseases of Plants	30–32
Agricultural Chemicals Approval Mark	31
Control of Diseases	32–33
Uses of Modern Weedkillers	33–34
Special Problems of Weed Control	34–35
Horticultural Societies	35
Finding List for Weedkillers	36–37
Care of Indoor Plants	38–40

MODERN GARDENING

CULTIVATION OF FLOWERS.

Throughout this section the notes must be taken to refer to cultural conditions in the British Isles, although in many cases the information can be adopted to suit the necessity of readers living abroad. Undoubtedly, in many temperate parts of the world interest in gardening has increased enormously during the past decade or so, despite the fact that numbers of large gardens have ceased to exist and that few people can afford to pay for full-time help in their gardens. To counteract this, the all important labour-saving garden has come into its own; shrubby plants have replaced annual bedding schemes and large lawns put down instead of herbaceous borders or beds of particular plants.

In addition, the owner-gardener is anxious to avail himself of the excellent selection of modern tools; thus the conventional hoe is being replaced by the "Swoe" or the Wolf pattern of Dutch weeder, both of which are very easy to use, and digging can be done quickly—and with much less effort—by using a German digger called a "Terrex" spade. For grass mowing, the work is easily done with the wide range of motor mowers to suit every purpose.

For greenhouse work, smaller houses are being used and one, say, 12 ft. by 8 ft., can be run economically with a minimum winter temperature of 40° Fahrenheit by the introduction of trouble-free, thermostatic heaters or the turbo-heaters. At the moment, besides automatic heating, the prototypes for automatic ventilation and watering are making an appearance.

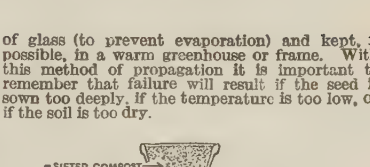
While advocating the use of such appliances, it must be pointed out that there are also to be found tools, sundries, and fertilisers of little value, and many of which have never been properly tested prior to being put on the market. It is, therefore, a good plan to discuss the comparative merits of any appliance or horticultural sundry with a competent horticulturist or to contact a public authority. In particular, many local horticultural societies have special trading facilities, and the merits of most garden things are generally known and discussed among members.

Throughout this Guide the vexed question of change in scientific name has been dealt with as liberally as possible and, whenever necessary, synonyms and cross references are given. In dealing with cultivar names, that is, varietal names like rose 'Peace,' reference is made as recommended in the *International Code of Nomenclature for Cultivated Plants* (1967). By so doing, the references are right up to date and further information on any particular plant or subject is easy to find. For the purpose, a few standard works of reference are given after each section. Normally, all the plants mentioned in the text are available through the usual trade channels.

After each plant listed there is a note on its propagation. Generally, this is the easiest or most efficient way of doing so, but it is not necessarily the only means. Details of the various methods employed are as follows:

Seed. Generally speaking, the early spring is the most suitable time for sowing seeds of trees and shrubs besides those of herbaceous plants and alpines. Where only a few plants are needed, the seed can be sown in pots and a suitable compost made up with 2 parts of soil, 1 part of peat, and 1 part of coarse sand. Before sowing, the pot should be stood up to its rim in water so that the soil is soaked. Then the seed can be sown thinly and covered with a light sprinkling of sifted compost.

For very fine seed, like begonias or azaleas, the seed must have only the merest "sugaring" of sand just sufficient to anchor it. When sown, the pots should be covered with a pane of glass (to prevent evaporation) and kept, if possible, in a warm greenhouse or frame. With this method of propagation it is important to remember that failure will result if the seed is sown too deeply, if the temperature is too low, or if the soil is too dry.



CORRECT PREPARATION OF SEED POTS AND PANS—Note provision for ample drainage and compost to rim of its container. After sowing, the containers are covered with a sheet of glass.

Cuttings. There are two main types of cutting: soft-wood cuttings made from fresh, green shoots in the spring and summer and hard-wood cuttings made of mature or semi-mature woody shoots in the autumn. A soft cutting is taken about 3 in. long, the lower leaves removed and a clean cut made through a node in the stem. These are then inserted in pots containing a light, sandy soil or a rooting medium such as horticultural vermiculite, well watered, and covered with a bell jar or plastic bag. Delphiniums, hydrangeas, and lupins are all propagated in this way.

Hard-wood cuttings are taken in the autumn and made from shoots about 8–12 in. long. These are inserted in a sandy soil out of doors or in a cold frame, and left to develop for a year. Black-currants, forsythia, and roses can be propagated by this means.

Layering. This is one of the easiest ways of propagating the majority of woody plants, and is used to increase stocks of plants like clematis, lilacs, and rhododendrons. Normally, layering is done in the autumn or spring when suitable branches are pegged down. On each of these the young shoots are, in turn, pegged down and tips turned upwards and tied in position. To encourage rooting, gritty sand and peat should be worked around each layer, and usually the young plant can be severed from the parent after about eighteen months.

Division. By this method it is easy to propagate the majority of herbaceous plants, some rock-garden plants, and a few shrubs. A few herbaceous plants, like delphinium and paeony, are slow to get established after moving, and here the method should not be employed. In any case, old plants should not be split up in a wholesale manner; instead, it is far better to select a few young healthy plants, divide these, and replant the best of the young shoots, in the autumn.

ALPHABETICAL LIST OF ORNAMENTAL PLANTS.

Abutilon.—The greenhouse species is often used in public parks for bedding schemes. *A. vitifolium*, with white, mauve, or blue flowers makes a fine wall shrub for warm gardens. If given full sun it will quickly reach 10–15 ft., but is sometimes short-lived. *Prop.*—Easily raised from seed sown in March in a warm greenhouse or frame.

Acer (Maple).—Hardy, ornamental trees; the Norway maple is often planted for its magnificent autumn colour and as a lawn tree. *A. palmatum* and vars. constitute the Japanese maples; all colour brilliantly in the autumn but do not grow freely unless given some shade and a light soil rich in humus. *Prop.*—Seed, layering, or budding.

Achillea (Yarrow).—Grey-leaved perennials for open border or, dwarf species, for rock garden. Valued as a cut flower, particularly *A. ptarmica* 'Perry's White,' with double, white flowers and *A. eupatorium* 'Gold Plate,' with large, flat, yellow flower heads. *A. millefolium* is a pernicious weed of turf (T34). *Prop.*—Division in autumn.

Acidanthera.—Scented, bulbous plant introduced from Abyssinia. It is not difficult to grow if the corms are planted in the spring and lifted in the autumn for storing in a frost-proof shed. It requires a sunny position and plenty of water in the summer. *Prop.*—Offsets removed when the old crop of bulbs is lifted.

Aconitum (Monkshood).—Blue-flowered perennial plants particularly useful for lightly shaded positions or full sun; flowers from May to July, height 3–5 ft.; roots poisonous. *Prop.*—Seed or division.

Adiantum.—*See* Ferns.

A Well-Grown Agapanthus—In winter the pot should be kept in a cold greenhouse or some protected place; in summer afforded full sun.

Agapanthus.—A bulbous plant, native of South Africa, usually found in seaside gardens and sometimes grown in tubs; flowers blue, violet, or white. It needs winter protection in the form of a covering of bracken or straw and a light soil heavily enriched with manure. Worthy of wider cultivation. *Prop.*—Seed or division in March.

Ageratum.—Blue-flowered carpeting plant. *See* Annuals.

Allium (Flowering Onion).—A genus of nearly 300 species of bulbous plants widely distributed over the Northern Hemisphere. The foliage has the distinctive smell of garlic, but some species are grown for garden ornamentation; in particular *A. roseum*, valuable late-flowering rock plant for dry positions. *Prop.*—Offsets, taken from parent bulbs in the spring.

Alstroemeria aurantiaca (Peruvian Lily).—This tuberous-rooted, herbaceous plant is often grown for cutting. Flowers orange-red and height 2–3 ft.; of easy culture if afforded a sunny position and left undisturbed. For best results apply liquid manure or soot water when growth starts. *Prop.*—Seed or division.

Althaea (Hollyhock).—A truly delightful, old-world plant, but not often seen, as modern hybrids have given way to rust disease. Best grown in a rich, heavy loam. Mulch with manure of any sort and stake as necessary. *Prop.*—Seed in June, thin out, and transfer to flowering position in September. Although a perennial, in some localities the best results are obtained by treating it as a biennial and raising a small supply annually.

Alyssum.—Low-growing annuals and perennials for rock garden and sunny border. The perennial, *A. saxatile*, is deservedly popular by reason of its bright, spring flowers and value as a wall plant. The variety 'Citrinum' is bright yellow and 'Dudley Neville' biscuit-yellow. *Prop.*—Perennial sorts by cuttings in June.

Amaryllis belladonna.—Often this plant is confused with the greenhouse, bulbous plant, *Hippeastrum*. The true amaryllis is a half-hardy bulb for planting at the foot of a warm wall; it has white to pinkish-red flowers. When planting, cover neck of bulb with an inch of soil and leave undisturbed, as the plant resents moving and is slow to get established. Lack of flowering is generally due to planting too deep. Established clumps may be fed with hoof and horn meal at 2 oz. per sq. yd. in July. *Prop.*—Divide and replant clumps in early July.

Amelanchier canadensis.—A large shrub or small tree; valuable for its spring flowers and autumn colour. As it will grow almost anywhere in sun or shade, it makes a good plant for informal screening. *Prop.*—Seed or layers.

Ampelopsis.—*See* Parthenocissus.

Anchusa italica.—A blue-flowered perennial with fleshy roots, growing to a height of about 3 ft. Responds to feeding and needs a position in full sun. *Prop.*—Root cuttings in the spring; division in the autumn.

Anemone.—The tuberous-rooted section includes the 'Caen' and 'St. Brigid' strains. These are best grown in an open position in light, rich soil; plant in October, lift and store when foliage dies. The hardy, fibrous-rooted perennials are varieties of *A. hybrida* (syn. *japonica*) and constitute one of the most accommodating of perennials, being particularly useful for damp, shady positions. Worthy of wider attention from gardeners. *Prop.*—Perennial sorts by division in autumn.

Annuals.—These are plants which develop from seed, flower, fruit, and die within a year. Additionally, some perennials, like antirrhinums, may be treated as annuals for the convenience of their cultivation. Sunny borders may be planted solely with annuals, they may be interplanted with perennials, used for window boxes, or, occasionally, in the rock garden. All sorts do best in well-worked, light loam enriched each year with a dressing of fish meal at 3 oz. per sq. yd., ten days before sowing or planting.

In the division of the group Hardy Annuals may be sown in the open ground as soon as conditions permit during March or April where the plants are to flower. Wet or cold soils will give many failures, and fine seed should be covered only with the lightest sugaring of soil. Often surprising—but delightful—results may be obtained by sowing broadcast mixed seed of annuals specially offered by some trade houses.

To raise Half Hardy Annuals, seed may be sown in early March in a warm greenhouse and the seedlings pricked out into boxes. Subsequently, the plants are grown on in a cold frame, gradually hardened off, and then transferred to their flowering positions towards the end of May.

Anthemis tinctoria.—Hardy perennial with feathery, grey foliage and flowers in varying shades of yellow. Height 2–3 ft., needs full sun and good for cutting. *Prop.*—Division in the autumn. *Anthemis nobilis* is the chamomile sometimes unwisely used to make lawns.

Antirrhinum (Snapdragon).—The popular bedding plant requiring a good soil and position in full sun now largely in disfavour owing to rust

disease; planting should be restricted to rust-resistant varieties. *See* Annuals.

Aphelandra squarrosa.—An evergreen, perennial plant introduced from Brazil. Often sold as a house plant, albeit a warm temperature and a high humidity are necessary for its cultivation. When grown indoors it is best discarded when the flowers fade and the foliage starts to wither, as it cannot be successfully grown on from year to year under normal conditions indoors.

Aquilegia.—The modern race of hybrids are the result of much interbreeding with wild forms to give a wide range of colours. Best when planted in light shade where soil is naturally moist. *Prop.*—Seed in late spring; transplant to flowering position for following year.

Arabis caucasica.—Once known as *A. albida*, this common rock plant is often used on dry walls. The double-flowered form is particularly good. *Prop.*—Cuttings in July; a fresh stock should be raised regularly as the special forms tend to die out.

Araucaria (Monkey Puzzle).—This tree was introduced from Chile, where it forms large natural forests, and widely planted in Victorian days. Browning of foliage suggests lack of water in the summer or, occasionally, effects of very cold weather. It should be planted in a position protected from the prevailing wind. *Prop.*—Seed in a warm greenhouse.

Armeria maritima.—A hardy perennial with pink or red flowers in the spring; must be grown in full sun where the soil is dry. *Prop.*—Division after flowering.

Artemisia.—A genus of shrubs and perennials suitable for sunny borders or rockeries. *A. lactiflora* is among the best of the herbaceous species, having grey foliage and creamy-white flowers. *A. abrotanum* (lad's love) in the shrubby section has grey, fragrant foliage. *Prop.*—Herbaceous section by division; shrubs by cuttings in the early summer.

Arundinaria.—*See* Bamboo.

Aster (Michaelmas Daisy).—By careful breeding this plant has been improved out of all recognition, and many first-class varieties are available in the trade. Responsive to good cultivation, it is used for its colour late in season and properties as a cut flower, particularly *A. yunnanensis* 'Napsbury' and *A.* 'Barr's Pink.' A wide range of colours are available besides some fine, low-growing forms. In the border one pleasing combination can be made with *A.* 'Harrington's Pink' and *Scabious* 'Dinkie.' *Prop.*—The clumps should be split up *annually* in the spring, and only the plumpest pieces of outer root replanted.

Aster, China or Common.—*See* Callistephus.

Astilbe.—Allied to the *Spiraea* and useful for planting in moist, rich soils; flowers white, pink, and crimson; height 2 ft. *Prop.*—Division of clumps.

Aubrieta.—A name often misspelt. Throughout the country it is used as edging or for dry walls. Many lovely sorts available apart from the commonly found, pale-blue variety. It is a lime lover. *Prop.*—After flowering the plants should be severely trimmed and, as necessary, stock increased by division.

Aucuba japonica.—Much maligned and overplanted shrub, but one tolerant of neglect and sunless or smoky conditions. Interesting variants of the type, like 'Crotonifolia,' may be found in trade lists. *Prop.*—Cuttings rooted in the open in July.

Auricula.—Correctly known botanically as *Primula auricula*. Flowers of alpine auriculas are white or yellow, while in those of florists' auriculas are to be found some of the most delicate colourings among hardy plants Choice varieties are grown in pots under glass; others in moist, shady borders. *Prop.*—Seed or division in the spring.

Azalea.—*See* Rhododendron.

Bamboo.—The common name for the large group of woody grasses, reference to which is difficult owing to the confusion in their nomenclature. Often grown for screening and wind breaks, and is a favourite shelter for small birds; the best for home-grown canes are *Phyllostachys viridi-glaucescens* and *Sinarundinaria nitida*. An interesting account of bamboo growing is found in the *Jour. Roy. Hort. Soc.* (June 1957). Growth can be encouraged by feeding with sulphate of ammonia and mulching with leaf-mould in the spring. *Prop.*—Division of clumps in late spring; transplants must be kept watered until established.

Begonia.—A genus showing wide diversity of form and much horticultural value. Of particular interest is the tuberous-rooted section, of which many of the loveliest varieties have originated in the nurseries of Messrs. Blackmore and Landon at Bath. For bedding schemes, the tubers are started in boxes of rich soil under glass in late March and planted out 9 in. apart in June. During the summer feed with liquid manure of any sort and keep moist in dry periods. *Prop.*—Cuttings in early spring in a warm case.

Berberis.—An extensive genus of beautiful and easily grown shrubs, evergreen and deciduous; the former used mainly for beauty of flower, and the latter for autumn colouring and ornamental fruits. *B. stenophylla* makes a fine evergreen hedge; invaluable for preventing illicit entry by dogs and, even, unruly children. *B. aggregata* and *B. jamesiana* are among the best berrying kinds. Prune in the winter by removing old wood. *Prop.*—Seed in spring or layering in autumn.

Buddleia.—Deciduous shrubs of easy culture for sunny positions. Varieties of *B. davidii* available in range of colours from purple to white; best when pruned hard by cutting all previous year's growth back to main stems in February. The weeping species, *B. alternifolia*, often grown as a standard; good specimens at R.H.S. Gardens, Wisley. This sort must be pruned in the summer by cutting off the dead flowering stems. *Prop.*—Cuttings in July–August in cold frame.

Cactus.—In the main grown in cool greenhouses or as house plants and, if cultivated well, many will flower every year. As a general guide, plants should be watered fairly freely in the summer and little in the winter, but there are exceptions. A detailed account of growing these fascinating plants will be found in *The Cactus Grower's Guide*, by Vera Higgings (Latimer House), 1946.

Calceolaria.—Seed of the greenhouse biennials sown in June or July for flowering in the following year. Mixed seed provides a wide range of colour. *C. integrifolia* is a half-hardy perennial, raised by cuttings or seed, for greenhouse or bedding work.

Calendula (Marigold).—This common hardy annual is freely raised from seed sown in August. Of easy culture in any sort of soil, although it is worth getting seed of new varietics now available. *See* Annuals.

Callistephus.—The China asters are among the best half-hardy annuals for garden and indoor decoration, but good soil and full sun are necessary for best results. *See* Annuals.

Camellia japonica.—Hardy, evergreen shrub rightly beloved by connoisseurs and cultivated in gardens for many centuries. May be grown in cold greenhouses, woodland gardens, and against north- and west-facing walls; under all conditions camellias must have a moist, acid soil. Best varieties for outdoors are 'Althaeaflora' (dark red), 'Donckelarii' (red, white marbling), and 'C. M. Wilson' (pink). Of recent introduction is the desirable *C. williamsii* bred from *C. japonica* in part; often the subject of television and gardening notes. The dropping of buds is thought due to dryness at the roots at some time

or sharp fluctuation in temperature. *Prop.*—Named varieties by cuttings under glass in early July. Otherwise plants easily raised from seeds if sown in the autumn immediately they are ripe, in acidic peat and kept moist.

Campsis grandiflora.—Sometimes found listed as *Bignonia* or *Tecoma*; choice deciduous climber for warm wall, large reddish-orange flowers in autumn. To encourage flowering growth, prune hard back to old growth in spring. *Prop.*—Cuttings in April struck in a warm case.

Canary Creeper.—*See* Tropaeolum.

Candytuft.—Hardy annual (*q.v.*) and perennials with white, crimson, blue, or purple flowers. The perennial—*Iberis sempervirens*—is a fine plant for a rock wall. *Prop.*—Seed or, perennials, from cuttings.

Carnation.—*See* Dianthus.

Centaurea (Cornflower).—The perennial species are valuable for cutting and border use, and may be found in such colours as pink, crimson, and yellow. *Prop.*—Lift and divide every third or fourth year. The hardy annual, *C. cyanus*, is often sold as a cut flower. *See* Annuals.

Chaenomeles speciosa.—This is the correct botanical name for japonica. The species commonly grown is a wide-spreading, rounded shrub, 6–10 ft. in height, and often used against walls. It is a plant of easy culture with best results being achieved by the annual spurring back of the current season's growth in the same way as an apple tree is pruned. All japonicas can be used for making jelly but, for this purpose, the best one is *Chaenomeles cathayensis*, a gaunt shrub about 10 ft. in height which bears fruit up to 8 oz. in weight. To obtain a crop within a reasonable time, two or three plants may be set in a group about 5 ft. apart. If growth or flowering is below par all japonicas should be fed with "Growmore" and mulched with compost.

Cheiranthus cheiri (Wallflower).—Among the finest displays of this biennial are those found each year in the public gardens of Southend-on-Sea, where it is used in conjunction with bulbs and forget-me-nots. *Prop.*—Seed sown thinly in rows in May and seedlings thinned or lined out and then transplanted in late autumn. The so-called Siberian wallflower, *Erysimum asperum*, which has bright orange flowers, is grown in the same way, but it is intolerant of wet soils. Both sorts are lime lovers, and on acid soils plants may receive treatment with 1 oz. of lime in a gallon of water.

Chimonanthus (Winter Sweet).—Hardy, winter-flowering shrub with heavily scented flowers. Although brought to this country from the Far East in the mid-eighteenth century its garden value is not widely appreciated. The large-flowered, yellow sort, *C. praecox*, is particularly fine, but like all the varieties, it is best grown against a sunny wall and where the soil tends to be poor. If growth is excessive and flowering poor, trim back young growth severely in March to encourage short, spur-like shoots. *Prop.*—Easily raised from seed or layers.

Christmas Rose.—*See* Helleborus.

Chrysanthemum.—Hardy annual sorts are available in a wide range of colours and give a fine display in the summer months. *See* Annuals. There are also a number of perennials such as the shafta daisy and the oxeye daisy for sunny herbaceous borders; all do well in ordinary soil, but should be lifted and split up about every three years. The plant sold by florists in the autumn is the Japanese chrysanthemum. Many are hardy out-of-doors, but no plant is more responsive to good cultivation and normally is best left to the specialist grower. For ordinary garden work, the best sorts are the Korean and Otley types. Under a brief reference the interesting details of cultivation cannot be dealt with fairly, and reference to specialist books is recommended.

Clematis.—A hardy climber for walls, screens, pergolas, and the like. Best kinds are to be found among named varieties in nurserymen's lists. A light, well-drained soil is necessary and if fed annually with a bucketful of manure or compost the plant will thrive for many years. Occasionally plants will be found on north walls, and if grown in full sun some light protection from the sun is desirable for the roots. Varieties which flower on the *current* season's growth, like *C. jackmanii*, should be pruned in late February to within a foot of the ground; other sorts should have sufficient old growth removed, after flowering, to keep them within bounds.

Sometimes the climber is killed by clematis wilt so premature death of young plants should not be automatically blamed on the supplier. Control is by spraying with a copper-containing fungicide. *Prop.*—Layering, by which means one shoot will often give three or four plants.

Convallaria majalis (Lily of the Valley).—Well-known perennial that will thrive in any damp, shady position. For best results lift every four or five years and mulch annually with old manure. *Prop.*—Division when foliage fades.

Coreopsis.—The hardy annuals are found in catalogues under "Callipsis," and all will thrive in ordinary soil. The flowers are mainly bright yellow, and many are good for cutting. *See* Annuals. Similarly, the perennials have the same predominant colour and are useful because of their long flowering season and abundance of flower. *Prop.*—Division.

Cornflower.—*See* Centaurea.

Cosmos.—Tall-growing, half-hardy annuals that are best grown in full sun in a dryish border. The large, daisy-like flowers can be had in a variety of colours, including white, yellow, pink, and crimson. *See* Annuals.

Cotoneaster.—Hardy evergreen and deciduous shrubs or small trees bearing scarlet or sometimes yellow berries in the autumn. All may be grown in ordinary or poor soil and planted in open or shady shrubberies and trailing species used against walls, over banks, or as ground cover. For shrubberies *C. lacteus* and *C.* 'Cornubia' with red berries and *C. rothchildianus* with yellow berries are among the best sorts; *C. conspicuus* 'Decora' is a strong grower for banks, while *C. horizontalis* is an excellent cover for any wall. Planting may be done in the autumn or spring, and no pruning, apart from occasional shaping, is required. *Prop.*—Seeds and layering.

Crataegus (Hawthorn).—There are many good varieties of our British hawthorn, *C. oxyacantha*, worthy of attention, particularly 'Coccinea' (crimson) and 'Paulii' (double, red). All will do well on poor soils, and no pruning is required. The common hawthorn makes a stout, impenetrable hedge planted 9 in. apart in a double row 9 in. asunder. *Prop.*—Common sort by seed; choice varieties by budding.

Crocus.—A hardy bulb of great beauty which was studied for many years by one of the best horticulturists of the twentieth century, the late E. A. Bowles. Does best in rich soil planted in bold groups around margins of beds or borders and naturalised in grass. When required, feed in early spring with bone meal at 2 oz. per sq. yd. *C. sieberi* and *C. tomasinianus* flower very early; the large-flowered, garden forms about three weeks later. *C. zonatus* flowers in the autumn and is often naturalised in grass. *Prop.*—Clumps may be lifted and divided about every five years, in July. The so-called autumn crocus is *Colchicum autumnale*. This bears large lustrous leaves in the summer, followed by mauve or white flowers—of fleeting duration—in the autumn.

Crown Imperial.—*See* Fritillaria.

Cytisus (Broom).—Only does really well in dry, poor soils in full sun; choice, procumbent sorts, like *C. kewensis*, used in rock gardens and tall ones

in open shrubberies. Pruning is important; shoots should be shortened after flowering, but old wood must never be cut. *Prop.*—Seed and cuttings in August in a sandy soil.

Daffodil.—*See* Narcissus.

Dahlia.—The cultivation of this plant is a special study, and there are probably more garden varieties of it than any other plant. Ordinary soil enriched with manure and an open position is required. Tubers may be planted 3 in. deep in April or young plants in late May. During the summer feed with soot water and liquid manure. After the first frosts lift, dry, and then store tubers in peat or straw in frost-proof place. Many stocks of dahlia are affected by virus (T30), and purchasers should be careful to check source of supply.

Daphne.—Shrubby plants, giving some of the most richly scented of all flowers. In particular, there is *D. mezereum*, which requires a damp soil; failure with the shrub is due usually to root disturbance or virus disease (T31) *D. odora* is one of the evergreen, fragrant species. Some references have suggested that this lovely shrub is not hardy, but there is no evidence to support the supposition. *Prop.*—Seed or layering.

Delphinium.—Hardy annuals and perennials. The latter sorts have gained popularity enormously since the War, due in the main to the activities of the Delphinium Society but also to the introduction of many very fine new varieties. American hybrids, like the 'Pacific Strain,' are very large but tend to die out and, consequently, lack the true, perennial habit of European sorts, albeit some of these have been weakened by the introduction of poor lines. It is important therefore to select stocks of strong constitution. Delphiniums need a deep, rich soil and a sunny position protected from wind. Plant in autumn 3 ft. apart, feed in the summer with liquid soot water, and mulch with decayed compost or manure in the spring. When growth starts, thin out weak growths to leave not more than five stems per plant. In winter take steps against possible slug damage (T29), and on this point it is beneficial to protect crowns with a covering of ashes. *Prop.*—Cuttings in the spring or seed; division of clumps is a poor alternative.

The hardy annual sorts are the well-known larkspurs, which grow to a height of 18 in. to 2 ft. and may be found in a range of colours including pink, red, white, and shades of blue. *See* Annuals.

Deutzia.—Hardy deciduous shrubs thriving in any soil and valuable for their summer flowers of white or whitish-pink shade. To keep the plants vigorous, shoots should be shortened after flowering and old or weak wood cut out. *D. scabra* is of robust habit, reaching about 7 ft., and *D. elegantissima* 'Fasciculata' proves a graceful shrub some 5 ft. tall with clusters of about twenty flowers coloured rosy-pink and each nearly an inch across. *Prop.*—Cuttings made from firm young growths about 10 in. long in sandy soil out-of-doors.

Dianthus.—This name covers a wide range of annual, biennial, and perennial plants. At one time often grown for their fragrance, but to a large extent this has been lost with the introduction of wider ranges of colour. Border carnations and picotees grown out-of-doors need a limy, fairly rich soil in full sun. Plant in the autumn or spring and, as the buds appear, feed with soot water or liquid animal manure, if necessary. These groups are *not* of good perennial habit and should be propagated annually to ensure continuation of stock.

The common pink requires the same soil conditions, and should be propagated when the stock gets weak; good scented varieties should be sought, and include the 'Imperial Pinks,' 'Mrs. Simkins,' and 'White Ladies.' *Prop.*—The best method is by layering in July so that the new plants can be put in their flowering position by mid-September. The lower leaves are pulled off selected shoots and a slit passing through a joint is made in the stem. Each layer is then pegged down with a hair-pin, the pin being placed above the cut. The layers are then covered with an inch of sandy compost and well watered.

In this genus is the sweet william; although truly a perennial, it is generally grown as a biennial and, consequently, the plant is raised from seed in May out-of-doors. In gardens where it is prone to rust disease control is most difficult and it is not worth a place.

LAYERING CARNATIONS—This is a typical example of how many plants can be propagated. A strong, new growth is pegged down into sandy soil after a cut has been made in the stem, at the point of pegging. Once rooted the layer can be severed from the parent and transplanted a week or two later.

Digitalis.—The biennial sort generally found in gardens is the common foxglove, which is grown in light shade in fairly rich, moist soil. In the past many named forms have been offered in the trade, but undoubtedly the best one is *D.* 'Sutton's Excelsior.' *Prop.*—Seed sown in May out-of-doors.

Doronicum.—Hardy perennials with yellow flowers; warrants wider planting, as they are among the earliest perennials to bloom and will thrive in poor soil or in some shade. The best is *D. austriacum* flowering in March, height 9 in. *Prop.*—Division after flowering.

Echinops.—Name appropriately derived from *echinos*, a hedgehog, in reference to the spiny, long scales of the flowers. The plant does well in an open position, where the globular heads of steely-blue flowers can be seen to advantage. *Prop.*—Division in March, but best left undisturbed as long as possible, as it must be moved with care.

Elaeagnus.—Hardy deciduous and evergreen shrubs generally grown in rather dry positions as foliage plants. Of the evergreen sort, *E. pungens* 'Aureo-Variegata' has bright golden variegation, and is therefore valuable for indoor decoration during the winter. *Prop.*—Layering in late summer.

Erica.—The heathers are native plants to Britain, and many variants found in the wild have been introduced into gardens to good purpose. Indeed, heathers have become so popular that special Heather Gardens have been made, and two fine examples may be found in the Royal Gardens, Windsor where the planting is new and the Royal Horticultural Society's Gardens, Wisley. Here, different sorts reaching the dimensions of small trees, dwarf kinds, and many scores of interesting variants, to supply flower throughout the year, will be found.

The Scottish heather is, botanically, *Calluna vulgaris*, and, like all British heathers, it is intolerant of lime or chalk. Where alkaline conditions exist, planters can try *E. carnea*—a winter-flowering heather—or *E. darleyensis*, but the results are usually disappointing. When planting all heathers, clumps must be well firmed and after-

wards kept moist; subsequently, mulch all types annually with peat. *Prop.*—Division and layering.

Erigeron.—Hardy perennial for sunny borders; daisy-like flowers freely develop and are good for cutting. *Prop.*—Division in the autumn.

Escallonia.—Slightly tender evergreen and deciduous shrubs. In the Midlands protection of a south wall is necessary; suitable for open shrubbery in the South. Ideal for maritime conditions, and here may be used to good effect as hedges. Many of the best varieties originated in the nursery of Messrs. The Slieve Donard Co. in County Down. *Prop.*—Cuttings under a glass jar in summer; layers in September.

Eschscholzia californica.—A hardy annual of easy culture; height 18 in., flowers mainly shades of orange. *See* Annuals.

Everlasting Flowers.—*See* Helichrysum.

Ferns.—A large number of plants are included under this name and, as they grow wild in many parts of the world, some need hothouse conditions. They are distinguished from flowering plants by their method of reproduction; instead of producing seeds, ferns develop spores, usually on the back of their leaves. The hardy kinds may be grown in equal parts of leaf-mould and soil, and the fronds of leaf-losing kinds should not be removed until the spring, as they offer some protection from the cold. Tender ferns should be repotted when new growth starts in the spring in a compost of equal parts soil, leaf-mould, and sand, using a pot just large enough for the purpose. During the growing season, in particular, keep the roots moist and plants free from a dry or smokey atmosphere. *Prop.*—Division of clumps when growth starts in the spring.

Forget-me-nots.—*See* Myosotis.

Forsythia.—Commonly found in many gardens, as it is of easy culture in any soil. Flowers bright yellow in early spring. To keep in good shape prune directly after flowering by cutting out old wood. *F. intermedia* 'Lynwood' is upright in growth and *F. suspensa* of weeping habit; both types make good wall plants for North aspects. *Prop.*—Cuttings in the autumn.

Foxglove.—*See* Digitalis.

Freesia.—Greenhouse bulbous plant and, if grown for scent, care must be taken to select fragrant varieties. Pot in the autumn in a fairly rich compost and keep as cold as possible until growth is seen. Then bring into a frost-free greenhouse and water freely. When flower stems appear, feed with liquid manure; after flowering, gradually dry-off until time for repotting. Failures almost invariably traced to premature forcing before root growth has been made or growing in excessively high temperature. *Prop.*—Offsets at potting time.

Fritillaria.—The one mainly used in gardens is *F. imperialis*, a handsome, spring-flowering bulb. To grow it *really* well, this species must be given a deep, rich soil and, contrary to some views, it is best lifted every year as soon as the foliage fades. If growth is poor or plants do not flower, feed when growth starts in the following spring with equal parts of bone meal and superphosphate at 3 oz. per sq. yd. *Prop.*—Offsets removed from parent bulb at lifting time. The old bulb should then be replanted at once and any offsets lined out in a nursery row.

Fuchsia.—Greenhouse and tender flowering shrubs. The outdoor sorts (of which *F. riccartonii* is the best) may be grown in light soil in full sun. In the spring prune all growth down to ground level; protect, if necessary, in winter with covering of cut bracken or dry straw. Greenhouse varieties are potted firmly before growth starts in the spring and, when buds burst, all the previous year's growth can be cut back hard. To encourage flowering, feed with a liquid manure, such as dried blood, and syringe foliage in hot weather. During the winter keep plants dry and house in a cool greenhouse. *Prop.*—Cuttings of new growth taken about 1 in. long and inserted in sand under a plastic cover in the spring.

Gaillardia.—Hardy annuals and perennials 18 in. to 3 ft. high which bear large, richly coloured flowers invaluable for cutting in mid- and late-summer. Unfortunately, on heavy soil the perennials are liable to die after flowering, and even on well-drained soils they cannot be considered long-lived plants. *Prop.*—Normally it is necessary to raise a fresh stock in alternate years; seed is sown in May in a cold frame and the young plants lined out in a reserve border prior to planting in the autumn.

Galanthus (Snowdrop).—Hardy bulbs well worth growing if given a moist, shady position where stock can be left undisturbed. Planting should be done in fairly bold clumps; bulbs are not expensive, and many variants, like double-flowered and tall-stemmed ones, are well worth a trial. *Prop.*—Lift and divide clumps in August.

Gentiana.—The gentians comprise some of the most fascinating of all rock-garden plants partly, perhaps, because some are difficult to manage. In particular, *G. acaulis*—which has true "gentian blue" flowers—is exacting in its requirements, and in many gardens flowering can never be induced. What controls flowering has not been discovered, and the plant can be grown well in acid or limy soils. On the other hand, *G. sino-ornata* must have an acid soil and is best in a position out of the direct sun. Beginners with the genus are advised to start with easily grown sorts, like *G. lagodechina* and *G. septemfida*. *Prop.*—Seed sown in cold frame in March or division in early spring.

Geranium.—The true geranium or cranesbill is a hardy floriferous perennial for rock garden or open border. In the latter case *G. ibericum* (blue flowers) and *G. sanguineum* 'Lancastriense' (rosy-pink flowers) are exceptionally good, and both do well in dry, sunny positions. The so-called "bedding" or "greenhouse" geranium is a pelargonium (*q.v.*). *Prop.*—Seed in March.

Gladiolus.—Dutch hybridists have done much work on this bulbous plant, and many new and lovely varieties are now available. The plant is responsive to good cultivation, and corms may be planted 4 in. deep and 6 in. apart during the spring in well-prepared ground. When the blooms fade remove the dead spikes of flower and lift the corms in September. After a month—and this point is important—pull off the old shrivelled corm and clean the new one. By doing this there is less likelihood of spores of diseases overwintering on the new stock. Finally, the corms should be stored in a dry, frost-free shed, and if given proper attention can be kept for a number of years. *Prop.*—Bulbils, removed when the corms are cleaned, can be sown in the spring in nursery rows and will flower within two years.

Godetia.—Hardy annual of easy culture and tolerant of poor soil conditions and even some shade. There are many varieties, mainly with bright flowers of rosy-pink and crimson. *See* Annuals.

Guernsey Lily.—*See* Nerine.

Gypsophila.—The favourite sort is *G. paniculata*, which is often grown for cutting, together with its double-flowered form, 'Bristol Fairy.' To do well gypsophila must be given a dryish soil which the roots can penetrate undisturbed; if growth is poor mulch in the spring with animal manure. *Prop.*—Generally done by seed in spring; special forms by grafting.

Hamamelis.—A lovely, but little grown, winter-flowering, heavily-scented shrub. The delicate, lemon-coloured flowers appear interminably from December to February. Although it flowers in its young stage, hamamelis is slow to get established and must be left free of root disturbance. The best sort is *H. mollis* introduced from China in 1879. *Prop.*—Usually by grafting; can be layered.

Heather.—*See* Erica.

Hedera.—Although ivy is seldom planted nowadays, there are a few evergreens to equal it for covering buildings. The large-leaved ivy with golden variegation, *H. colchica* 'Dentato-Variegata,' is invaluable for cold or shady walls. *Prop.*—Cuttings in August in shady border out-of-doors.

Helianthus.—The perennial sunflowers are tall, yellow-flowered plants of vigorous habit. They spread quickly and become a nuisance, and therefore clumps should be lifted and single, rooted pieces replanted every other year. The annual sunflower may reach a height of 10 ft. or so; seed is sown out-of-doors in April or seedlings raised under glass in the spring. When the flower bud appears, feed with soot water. The seed may be used as food for large birds like parrots.

Helichrysum.—Although this is a large group of plants, the most interesting is the half-hardy annual, *H. bracteatum*, the everlasting flower. When the flowers are fully developed they are cut with long stems and hung up to dry for winter decoration. *See* Annuals.

Heliotropium peruvianum (Cherry Pie).—Scented, shrubby plants used for greenhouse decoration or summer bedding. *H.* 'Sir Edward Fry' is among the scented varieties and *H.* 'Princess Marina' is the best dark-purple variety. For really good results, heliotropes need a rich soil and plenty of water in summer. *Prop.*—Cuttings 2–3 in. long in early autumn or spring, struck in sandy loam in a warm greenhouse.

Helleborus.—The Christmas rose, *H. niger*, should be planted out of the direct sun in a moist soil which has been liberally enriched with leaf-mould and old manure and here left free from root disturbance. Its large, white flowers appear irregularly from December to February with early flowering encouraged by protection with cloches. The Lenten rose, *H. orientalis*, flowers from February to April, and it is well worth searching nurserymens' lists for varieties with a wide range of colours. *Prop.*—Division of clumps in the spring, with each piece having four or five growth buds; the clumps should not be split into small pieces.

Hemerocallis.—Hardy perennial for moist border either open or slightly shaded. Mulch established clumps in the spring with compost or manure. Many new varieties are coming on the market as a result of introductions from America, where the plant is popular. *Prop.*—Division.

Hibiscus.—The evergreen, shrubby sorts with large exotic flowers are widely grown in the tropics and can be seen under glass in botanic gardens in Britain. *H. syriacus* is a deciduous, hardy species; little pruning is required, and in full sun it will reach 8–10 ft. Normally, it is a free-flowering plant of great beauty and, in cases where the flowers fail to develop, the stock is best replaced with good varieties, like 'Coeleste' (single, blue) and 'Woodbridge' (single, red). *Prop.*—Cuttings under glass; grafting.

Holly.—*See* Ilex.

Hollyhock.—*See* Althaea.

Honeysuckle.—*See* Lonicera.

House Leek.—*See* Sempervivum.

Hyacinth.—Bulbs generally used for bowl culture; often results are disappointing, but responsibility does not necessarily rest with the nurseryman, as poor cultivation is the most probable cause. Plant in September–early October (not later) in peat, loam, and sand, and keep as cool as possible until growth starts, when bowls may be brought into a warm room. Care must be taken with watering, as the bulbs must not dry out nor the compost allowed to become wet and soggy. After flowering, plant out-of-doors and lift annually in June for replanting in the autumn; for bowls a fresh stock is required every year. Failures are mostly due to late planting or faulty watering.

Hydrangea.—A favourite shrub introduced from the Far East. Of the many forms, the one offered by florists, *H. macrophylla*, is the most popular. This can be bought in a wide range of shades, from white and pink through to crimson and blue. The colour will depend on soil reaction; in alkaline or neutral soils *only* white and pink shades can be grown, and blue flowers will be found *only* on acid soil. The intensity of colour can be improved by adding lime in the first instance and flowers of sulphur in the second, but it is not possible to make an alkaline garden soil acid in reaction. Lack of flower is generally the result of buds being killed by cold weather. For this reason, hydrangeas are best not pruned until the late spring; then old flower-heads and any weak or unwanted growth can be cut out. During the summer the plants must not suffer from lack of water.

Among the many other sorts are *H. paniculata*, with large, cone-shaped panicles of flower and *H. petiolaris*. The latter plant is a vigorous climber, well suited to cover cold walls or for climbing over dead trees. *Prop.*—Cuttings in July–August in a cold frame.

Iberis (Candytuft).—The hardy annual sorts will thrive in any soil, and may be had in a range of colours. *See* Annuals. The perennial candytuft (*I. sempervirens*) is a good plant for a rock wall and has white flowers in early spring. *Prop.*—Seeds in spring and cuttings in summer.

Ilex.—The ornamental value of our native holly is rarely fully appreciated, bearing in mind that, on good varieties, the berries sometimes persist until March. The greenish flowers are sometimes bisexual, and sometimes male and female flowers are on *separate* plants. For this reason hollies should be planted in groups, and at least one plant of good berrying habit, like *I. aquifolium* 'Pyramidalis,' grown. Some varieties have yellow berries and gold or silver variegations on their leaves. *Prop.*—Seed; special forms by budding.

Iris.—This plant is divided into two main sections: those types which grow from bulbs and those which grow from fleshy rhizomes, with many subdivisions in each of them. Of the latter type, there are the commonly grown bearded flag irises, which, owing to their ease of cultivation and wide range of colours, are appropriately known as the poor man's orchid. Notwithstanding, these irises respond to good treatment, doing best in well-dug soil to which a little manure has been added and a dressing of rough chalk forked into the surface. The site should be in full sun for preference and one that never lies wet in winter. Planting or division of established clumps is done in July, setting the rhizome on the surface of the soil but firming the roots well. To maintain growth and flower, feed annually in the spring with equal parts of superphosphate and bone meal at 3–4 oz. per sq. yd. Iris gardens are not often found nowadays, but the fine example still maintained at Kew is well worth close inspection.

In the bulbous section the Siberian iris is a graceful plant with delicate foliage, though much smaller-flowered than the flags. They make a fine waterside planting or may be grown in the herbaceous border. The Japanese iris is another water lover, and this has delicate-coloured, clematis-like flowers. On the other hand, for dry, poor, stony soils in full sun the lovely, winter-flowering, Algerian iris, *I. unguicularis* (*stylosa*), is an ideal plant, flowering as it does in December and January. This is a plant which must be left undisturbed after planting in June and if leafy growth is excessive the foliage can be cut back by half in August. Spanish, Dutch, and English types of bulbous iris are often used as cut flowers. These may be planted in ordinary garden soil in the autumn and left undisturbed until signs of deterioration are found.

Japonica.—Common misnomer of *Chaenomeles*, (*q.v.*).

Jasminum.—The yellow-flowered, sweetly scented winter jasmine blooms intermittently

from November to February. It grows in any soil, and is best trained up a wall or grown on a trellis. Pruning consists of cutting out the flowering shoots as soon as the blossoms fade. The summer jasmine is a vigorous climbing plant with white, scented flowers. It needs a sunny position and should be well thinned after flowering. *Prop.*—Layering in summer.

Kalmia.—Hardy American shrubs with clusters of waxy, rose or pink blossoms in early summer. Although slow to get established and requiring a damp, acid soil, the plant is well worth growing. It constitutes a feature of the gardens of the National Trust at Sheffield Park, Sussex. *Prop.*—Seed or layering.

Kerria japonica.—A hardy shrub which will thrive in any garden but is best fed with manure to encourage strong growth. When the yellow flowers fade, the stock should be kept vigorous by cutting out old or weak growth. The plant is named after William Kerr, a young man despatched from Kew to collect plants in China. *Prop.*—Division in autumn.

Kniphofia (Red-hot Poker).—Although these plants are so commonly seen, their full value as late-flowering subjects is not often fully explored. There are a number of good varieties worth growing, such as 'Maid of Orleans' (white, 4 ft.), 'Mount Etna' (scarlet, 5 ft.), and 'Royal Standard' (gold and scarlet, 4 ft.). Of equal value is the dwarf variety with grass-like foliage, *K. nelsonii*. *Prop.*—Division in March; easily raised from seed if so desired.

Laburnum.—Handsome trees with long racemes of yellow flowers, the seeds of which are very poisonous. It is not advisable to remove branches, as wounds do not heal well or quickly, and once a specimen shows signs of deterioration it is best replaced with little delay. *Prop.*—Seed or grafting.

Larkspur.—*See* Delphinium.

Lathyrus (Sweet Pea).—For general garden decoration, seed may be sown in pots in a warm greenhouse in early February prior to transplanting out-of-doors in April. When heat is not available sowing can be done in the open in October, setting the seed 4–6 in. apart and 2 in. deep where the plants are to grow. In this case the rows are best protected by cloches. As the plants flower with great freedom and make strong growth, a rich, deep soil is required. During the summer water should be given freely and liquid animal manure or soot water applied weekly when flowering starts. When raised for exhibition, special cultural treatment is necessary. The cause of the condition referred to as bud drop is not known, but it is thought to be connected with low temperature and faulty root action.

There is also the hardy, perennial sweet pea, an old-world plant usually seen at its best in cottage gardens. This plant requires the same cultural conditions, except that the old stems are cut down in the autumn. Three or four different species are available, and all are easily raised from seed sown in the spring.

Lavandula.—The lavender is one of the best known of garden plants. It thrives in full sun in a light soil; old flower heads should be clipped off in the summer, but any cutting back into old growth must be left until the spring. The best garden form is *L. spica* 'Nana Atropurpurea'; it has a neat, dwarf habit, with deep purple flowers, and is available from leading nurserymen. *Prop.*—Cuttings out-of-doors in August–September.

Leucojum.—The spring snowflake flowers in February and is a charming plant for any damp, shady border. Although it has a large flower, it has never become as popular as the snowdrop, despite its ease of culture. It should be grown by everyone who values early spring flowers. *Prop.*—Lift clumps and replant after removing offsets in August.

Lilac.—*See* Syringa.

Lilium.—The lilies constitute a large genus of plants, some of easy culture, some demanding the most exacting of conditions. For a soil containing chalk two of the best lilies are *L. candidum*, the Madonna lily, and *L. regale*. The former is a feature of many gardens in South Wales, where bulbs are planted near the surface of the soil and the clumps eventually left to develop undisturbed. Only the easiest-grown lilies are suitable for the herbaceous border and, here, apart from the Madonna lily, the tiger and martagon lilies should be first choices for beginners in the cultivation of this genus. *Prop.*—Those referred to above may all be raised from seed sown out-of-doors (or in deep boxes in a cold frame) in the spring. In the following April line out into nursery rows prior to transplanting to flowering positions. Also propagated by offsets and bulbils.

Lily of the Valley.—*See* Convallaria.

Lobelia.—The bedding lobelias are perennial plants best raised as annuals (*q.v.*). They do well in a light soil, but should be firmed at planting time to prevent plants dying off during a hot spell. The handsome, tall-growing lobelias with scarlet flowers, like *L. fulgens* 'Huntsman,' may be used in herbaceous borders with great effect, but the roots must be lifted and overwintered in a cold frame. These sorts grow to a height of 2–3 ft. and will do well only on a wet, heavily manured soil.

Lonicera.—The honeysuckles make effective climbing plants if grown on the shady side of arches or tree stumps or against north or west walls. Care should be taken to train young growth before it becomes hard. Old shoots may be cut out each spring to keep the plant within bounds, although space must be available for free development. If growth and flowering is poor mulch the roots in the spring with old manure. *Prop.*—Easily done by layering in late summer.

Lupins.—There are two sorts of lupins, perennial and annual. The herbaceous perennials are among the most colourful of plants as a result of the famous 'Russell' strain being introduced. Of late years, however, the constitution of the plant has been weakened through, perhaps, breeding and virus diseases, and it should be taken for granted that most stocks have to be replaced every two years or even annually in some cases. The plant requires a rich soil and is best in ground free of lime. Conversely, in poor soil the tree lupin thrives and will reach a height of 7–9 ft.; plant in full sun and lightly prune into shape after flowering. *Prop.*—Both sorts are best raised from seed sown in May out-of-doors and transferred to flowering positions in October. The annual lupin may be obtained in a range of colours, and should be grown in full sun. *See* Annuals.

Magnolia.—Rightly said to be one of the most beautiful of all flowering plants. Contrary to popular belief, some kinds are of easy culture, flowering when young and suitable for small gardens. Of course, careful selection is necessary and for a specimen on a lawn *M.* 'Soulangeana' (large, white or white, purple-stained flowers) is ideal. *M. stellata* freely flowers in the young stage, and may be planted in an ordinary border if the soil is lime free. To encourage growth, mulch annually with peat or leaf mould, but never dig near the roots. The evergreen magnolia is often seen as a fine wall plant in old gardens. This is the only species which may be pruned, and long shoots can be cut back hard in April. There are a number of non-flowering strains of the evergreen one, and unsatisfactory plants are best destroyed, as flowering cannot be induced; in buying a replacement care is necessary in order to avoid *another* dud. *Prop.*—Seed sown as soon as it is ripe in October; layering.

Mahonia.—Hardy evergreen shrub of great merit if grown well. *M. aquifolium* is useful as ground cover, thriving in any soil and in shade if protected from cold winds. *M. japonica* has long racemes of lemon-scented flowers in winter; inferior sorts are often listed by nurserymen under this name. Of equal merit is *M.* 'Charity'

which by reason of its flowering in November warrants a place in any garden if free from exposure to wind. Foliage sought after by flower arrangement groups. *Prop.*—Seed, suckers, layers, cuttings in August.

Mathiola.—The night-scented stock is a hardy annual with insignificant purplish flowers which open at dusk; grown primarily for its perfume. Conversely, the so-called Ten-Week stocks and a selection of these, the East Lothian stocks, have a wide range of colours. If sown in March they may be used for summer bedding or if sown in August overwintered in a sunny frame and grown as a biennial.

Brompton stocks flower earlier than the other sorts, and are grown as a biennial by sowing seed in June or early July and, after pricking out into boxes, are overwintered in a sunny frame. In mild districts, if the soil is well drained, stocks may be planted out-of-doors in the autumn, but a reserve should be kept for filling up gaps in the spring.

Meconopsis.—This genus includes the famous "blue poppy," introduced from the Himalayas. It is not a plant of easy culture, albeit large groups are grown in many woodland gardens where soil conditions permit. After flowering the plants generally die, although an occasional plant may persist. *Prop.*—Seed sown in March.

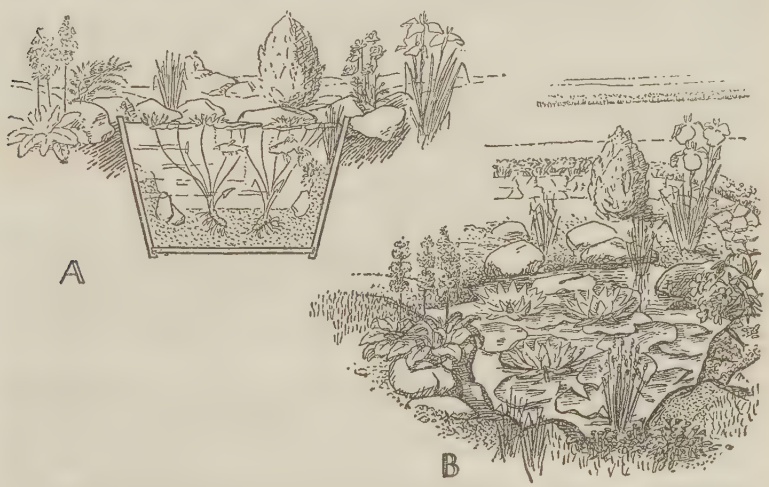
Michaelmas Daisy.—*See* Aster.

Montbretia.—This bulbous plant is of easy culture and has a long season of flowering. Many new varieties with large flowers are now available, and growth can be kept vigorous by lifting and dividing the clumps every three or four years. Plant in early spring 4 in. deep and 6 in. apart and in cold gardens protect clumps in winter with a covering of ashes.

Myosotis.—The forget-me-not is grown as a biennial by sowing seed in May and planting out in the autumn in conjunction with spring-flowering bulbs and wallflowers. Poor varieties freely establish themselves, and these should be destroyed before planting any of the really good sorts offered by seedsmen.

Narcissus.—This botanical name includes plants commonly known as "daffodil" and "narcissus." Although often grown, the wide garden value of these spring-flowering bulbs is not fully realised, as by careful selection of varieties a long season of flower can be obtained when they are grown in formal borders or naturalised. Thus, a season may be extended with 'Peeping Tom' and 'Covent Garden' (early) and 'Geranium' and 'Buttermilk' (late). The bulbs can be left undisturbed until flowering is affected by over-crowding; the clumps should then be lifted and be divided in the late summer. To maintain vigour, feed annually in February with 2 parts bone meal, 1 part hoof and horn meal, and 1 part sulphate of potash at 2–3 oz. per sq. yd. The chief troubles with narcissi are due to eelworm (T29) and the narcissus bulb fly (T28). For indoor work, plant in bowls in October and keep in cold place until growth is an inch high; failure is invariably due to premature forcing or faulty watering.

Nasturtium.—*See* Tropaeolum.



WATER LILIES IN TUBS—Drawing (A) shows a cross-section with correct percentage of water and soil together with water lilies and fish. Drawing (B) illustrates marginal planting with primulas, Japanese irises, and a dwarf coniferous tree.

Nepeta (Catmint).—In recent years this edging plant with silvery foliage and mauve flowers has become increasingly popular. When flowering in mid-summer there is no finer display of colour. It grows freely on any light, well-drained soil in full sun. The best sort is *N. faassenii*. *Prop.*—Division of clumps in March.

Nerine.—Lately this lovely bulbous plant has increased in popularity mainly through the varieties introduced from the late Lionel de Rothschild's garden at Exbury. The hardy sort *N. bowdenii* flowers in the autumn and should be planted at the foot of a warm wall in August or September and left undisturbed for many years. As the bulbs gradually multiply and work to the surface, a light dressing of sandy compost, to which has been added a little bone meal, can be applied. *Prop.*—Separation of bulbs in August.

Nicotiana (Tobacco Plant).—This half-hardy annual is grown mainly for its heavily scented flowers, which open in the evening. It is worth remembering that the white-flowered sorts are the best in this respect; scarlets and pinks are very much inferior. *See* Annuals. The tobacco of commerce is a different plant, namely, *N. tabacum*.

Nymphaea.—No branch of gardening is more fascinating than the water garden, and for it the chief plant must be the water lily. Basically, the main reason for failure is in the fact that in most pools the *average* depth of water is less than 18 in.; this means that the water is liable to be adversely

affected by extremes of temperature. All nymphaeas should be grown in full sun and where the water is still; in streams it is necessary to utilise a little backwater out of the current. Water lilies are planted in May in large wicker baskets with a compost of three-quarters of loam and a quarter of peat; alternatively, planting sites can be built up with bricks to the desired height. If growth is poor, mould "Clay's Fertiliser" into the size of pigeons' eggs and drop one around each clump. To maintain a healthy condition in the water, fish should be introduced as soon as the plants are established. *Prop.*—Division of tuberous roots in late May.

Orchids.—In the main, this large group of plants needs greenhouse conditions and specialised knowledge. Their cultivation has attracted the attention of some of the greatest of horticulturists, and detailed references may be found in books like *Orchids, their Description and Cultivation*, by C. H. Curtis (Putnam), 1950.

Paeonia.—There are two sorts of paeony, the tree paeony and the herbaceous paeony. The former needs a sheltered, warm position and takes about three years to flower from planting time. The latter sort needs a moist, rich soil, and should be mulched annually in the spring with well-rotted manure; some are known not to flower, and as such plants cannot be induced to do so they should be destroyed. The old-fashioned variety of paeony has been superseded by many fine new varieties found listed by specialists. *Prop.*—Tree paeonies by layering or seed sown in the autumn; herbaceous sorts by seed or division.

Pansy.—*See* Viola.

Papaver (Poppy).—The oriental poppy is a hardy herbaceous perennial with striking flowers, intolerant of shade and root disturbance. As it blooms early, it should be set near the back of a border, as the large leaves look untidy later in the year. Apart from the commonly grown, red-flowered sort there are others in shades of crimson, pink, and lavender. *Prop.*—A wide range of colours can be obtained by sowing mixed seed in May. This is a better method than division. The Shirley poppy is a hardy annual (*q.v.*), while *P. nudicale* is a biennial needing a warm, sheltered position.

Parthenocissus (Virginia Creeper).—This climber, with its brilliantly-coloured leaves, makes a fine sight in the autumn, and there is no better plant for covering brickwork or unsightly buildings with a south or west aspect. It has been suggested (mainly by builders) that the plant will damage stonework or cause dampness. There is little evidence to support these suppositions, and reasons for damage can usually be traced—often without difficulty—to other sources. The plant has had a number of names—*Ampelopsis veitchii* is one—but up-to-date nurserymen are listing it correctly as *P. tricuspidata*. *Prop.*—Cuttings out-of-doors in the late summer; layering.

Passiflora caerulea (Passion Flower).—A south wall in favoured gardens is needed to grow this plant. It is of vigorous habit and, once the framework of branches has been produced, it should be pruned annually in the early spring, by cutting back all the previous season's growth to 2–3 in. of the main stem. *Prop.*—Layering.

Pelargonium (Geranium).—So-called "bedding geraniums," such as 'Paul Crampel,' are really zonal pelargoniums. To maintain a stock, take cuttings in early August and insert in sandy soil around the edge of a pot and overwinter in a frost-free greenhouse. In the spring pot-up singly and use for bedding. Otherwise pot-on after two months and, if early buds are nipped off, plants can be adopted for late flowering indoors. Pelargoniums are easy to grow, but for best results a position in full sun is necessary, and cuttings should be rooted *before* the autumn so that overwintering constitutes no great difficulty.

Petunia.—Although really perennials, these plants, native of South America, are treated as annuals (*q.v.*). They are sun lovers and do best on light soils. Petunias make fine plants for sunny window boxes, and particularly happy combinations can be made by planting together varieties such as 'Violacea' (deep violet) and 'Cheerful' (pale pink) or 'Flaming Velvet' (crimson) and 'Cream Star' (pale cream). The violet-flowered sorts are faintly scented.

Philadelphus (Mock Orange).—Although some fine varieties of this shrub are available in the trade, it is not grown as widely as its merit deserves. As a scented shrub it has few equals, while it is tolerant of poor soil conditions and shade. Particularly good sorts worth searching for are 'Albatre' (double), 'Beauclerk' (single), and 'Sybille,' which, at 3 ft., is about half the height of the others. After flowering, prune annually by removing as much old flowering wood as possible. *Prop.*—Hard-wood cuttings out-of-doors in November.

Phlox.—A wide range of varieties of the border phlox are offered to make an impressive display late in the season. If grown on light soils some shade is desirable, as phloxes do well where only the soil is damp. For this reason, mulching should be done annually in the spring with compost or animal manure. Failures are usually due to eelworm (T30). *Prop.*—Seeds in autumn; division.

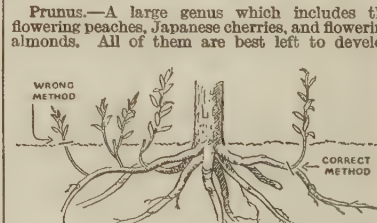
Poppy.—*See* Papaver.

Polyanthus.—*See* Primula.

Polygonum.—In the main these plants are weeds of gardens, although originally they were introduced from the Orient or ornamental purposes at a time when their invasive habits were not fully appreciated. The one woody climber in the genus, *P. baldschuanicum*, makes an admirable cover where a very vigorous plant is wanted. Rampant and unwanted species may be eradicated by hormone treatment (T34).

Primula.—Polyanthuses, primroses, greenhouse primulas, and the hardy primulas all belong in this genus. The first two are the most popular; both will do well only in damp soil and respond to generous manurial treatment; both are available in a wide range of colours. *Prop.*—The Blackmore and Langdon strains of seed will give a magnificent display of mixed colours. Sow in warm greenhouse in early March or cold frame in April; prick out into boxes and transfer to flowering positions in the autumn.

Prunus.—A large genus which includes the flowering peaches, Japanese cherries, and flowering almonds. All of them are best left to develop



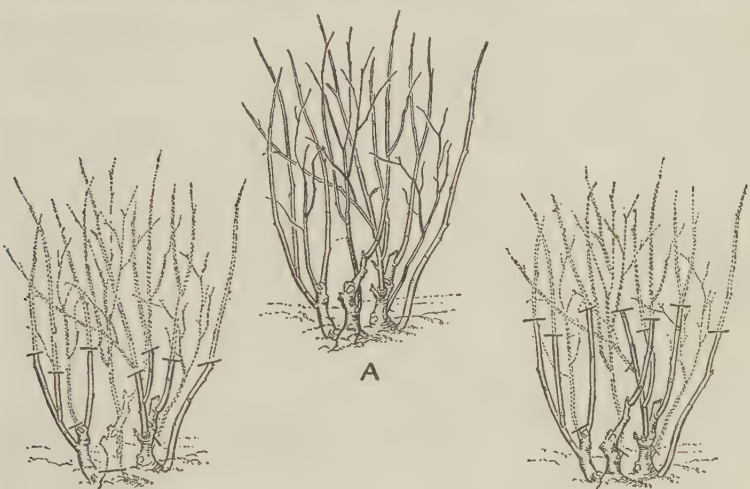
REMOVAL OF SUCKERS—As illustrated, these must be sawn off into the root or pulled off the root with a sharp tug and never so removed that dormant buds are left.

naturally and are not responsive to pruning or cutting back in any way. A few sorts are over-planted in gardens and as street trees (by Park Superintendents), but anybody wishing to be a little out of the ordinary would do well to see the wide range of some of these lovely trees flowering in April and May in our botanic gardens and many of the large gardens now under the jurisdiction of the National Trust. The selection offered by nurserymen is often strictly along conventional lines. Lack of flower in some seasons can often be traced to bird damage.

Red-hot Poker.—*See* Kniphofia.

Rhododendron.—Greenhouse and hardy, evergreen and deciduous shrubs, including *Azalea*. With something like ten thousand different sorts, it is impossible to deal with individual requirements. General cultivation; an acidic soil is essential, with adequate moisture in summer. If growth is poor on established plants, mulch liberally with animal manure. Beginners should plant from the accepted list of hardy garden hybrids. Since the turn of the century widely planted and fine examples are to be found, for instance, in many gardens of the National Trust. *Prop.*—Seed and layering.

Romneya.—Since its introduction from California in about 1850 the plant has proved a fascination to gardeners, as sometimes it fails completely or does exceedingly well. It apears to require a light soil and a sheltered position, preferably against a sunny wall, and there is no point in trying to grow a romneya on a heavy, wet soil. Usually the annual stems die off in the winter and may be cut down at ground level in the early spring; if persistent the stems can be cut back to sound growth. The new growth is susceptible to slug damage, and appropriate steps must be taken (T29). *Prop.*—Seed or suckers taken off in the spring.



PRUNING ROSES—(A) A vigorous unpruned plant. (B) The same plant pruned for the production of exhibition blooms, (C) and pruned for garden decoration.

Rosa (Rose).—Undoubtedly the rose is the most popular of all garden flowers, and it may be found in a multitude of forms. The dwarf roses for bedding may be grown on most soils, but are best on a rich, heavy loam. Planting is done from early November onwards when soil conditions permit and the first pruning carried out in the following spring, when the extent of any winter damage can be seen. Opinions differ sharply on pruning; a sound, general rule is to do the work in March and—unless there are special circumstances—to prune on the light side. Thus, for Hybrid Teas and the like, reduce strong stems by about one-third of their length, medium ones by a half, and weak ones to within two or three buds of the main stem.

Whatever sorts of soil roses are grown in, feeding is important, but, of course, it is particularly so on poor ones. It is in soils of *low* fertility that diseases such as rust and black spot are most prevalent and, in some measure, persistence of the disease is due to bad cultivation and lack of treatment with fertilisers. Regular dinocap sprays will control mildew provided the bushes are well mulched and watered. Captan or maneb should be used immediately after pruning and throughout the summer to control black spot, but thiram for rust control need not be used until the disease appears. Good manurial treatment including foliar feeding will help to *prevent* disease. For control of greenfly *see* Aphids, T29.

For a manurial programme, an application of 2 parts of superphosphate and 1 part of sulphate of potash should be applied at 3 oz. per sq. yd. after pruning. Following this, a surface mulch of animal manure, compost, peat, or leaf-mould or a mixture of all of them is given about 2–3 in. thick. Subsequently, if growth is poor, a dressing of nitrochalk can be made at 1 oz. per sq. yd.

Where soil conditions are poor and disease prevalent, it is important to buy plants only from nurserymen who take special precautions to ensure that their customers have disease-free stock. Likewise, varieties of robust constitution are essential, and a selection list may include: *Hybrid Teas:* 'Ballet' (pink), 'Eden Rose' (magenta pink, 'King's Ransome' (yellow), 'Perfecta' (pink and white), 'Super Star' (coral orange) and 'Wendy Cussons' (rosy red), *Floribundas:* 'Circus' (bicolour yellow/scarlet), 'Dusky Maiden' (crimson), 'Iceberg' (white), 'Queen Elizabeth' (pink) and 'Spartan' (deep salmon).

In most of the modern hybrids scent is almost absent. The true rose perfume is found only in the Old Fashion or shrub roses and, normally, these are planted in a mixed shrub border. For the richest perfume varieties like 'Alba Celestial,' 'Mrs. John Laing' and 'Conrad F. Meyer' should be sought.

Salvia.—Annuals, perennials, and tender shrubs. The most popular one is the scarlet sort used for bedding. It requires careful attention, and seed should be sown in February in a temperature of 60° Fahrenheit and seedlings put into single pots when large enough. Gradually the young plants are hardened off and finally planted out in rich soil in a sunny bed.

Saxifraga.—A large genus of plants suitable for the rock garden and valued for their bright flowers in the spring. The encrusted saxifrages are cushion-forming plants requiring sharp, surface drainage and an open position out of the direct

sun. The mossy saxifrages are mat-forming in growth and of easy culture. In time old clumps develop brown patches and then require splitting up and replanting in the spring.

Scabiosa.—The commonly grown perennial sort is *S. caucasica* and is invaluable as a cut flower. It is not at home on all soils, and only does really well in a deep, rich loam containing plenty of chalk. In addition, it must be grown in full sun and particular care taken against slugs. *Prop.*—Old plants divided in the spring and rooted pieces replanted in their flowering positions. A wide range of shades in white, blue, and purple can be had normally from sowing mixed seed in April.

Sedum.—The stonecrops make up a large group of hardy and tender plants, but comparatively few are of horticultural value. Notwithstanding, *Sedum spectabile* is to be found in most herbaceous borders, where its fine, flat heads of pink flowers are a feature for many weeks. It is beloved by bees and butterflies. *S. sieboldii* was introduced from Japan about 100 years ago and, although hardy, it is usually grown as a house plant. In the winter it can be stood out-of-doors, and every two or three years repotted in the spring; keep well watered during the summer and feed with liquid manure occasionally. *Prop.*—Division in the spring.

Sempervivum (House leek).—These hardy plants with succulent leaves often decorate the crevices of old walls and are regular features of trough or sink gardens. If given a light, poor soil and a position in full sun a fascinating collection of house leeks can be built up. The species which gives the plant its common name can be established easily on a sunny roof by planting in a mixture of cow manure and clay during the spring. *Prop.*—Division in the spring.

Skimmia.—A hardy evergreen 2–3 ft. tall which is tolerant of shade and some degree of dryness. If growth is poor water with a liquid manure and mulch with peat or leaf mould. Some forms bear only male flowers and to ensure a good crop of berries plant an hermaphrodite like *S. foremanii*. *Prop.*—Layering in the autumn.

Snowdrop.—*See* Galanthus.

Snowflake.—*See* Leucojum.

Solanum capsicastrum (Winter Cherry).—A berrying plant with bright-red fruits which is often used for house decoration. To maintain the plant in a healthy condition it should be clear of draughts and fumes of gas fires and the foliage kept fresh and free of dust by vigorous syringing. If the stock is to be kept for more than one season water should be given only sparingly in the New Year, and in early March all the side shoots pruned back hard to within a bud or two of the main stems. As new growth develops, water can be given more freely and syringing started when the flowers first appear; liquid manure will prove beneficial when berries develop.

Spiraea.—Hardy deciduous shrubs for open borders; tolerant of poor soil conditions. The commonly grown one is *Spiraea bumalda* (syn. *japonica*). After flowering, a percentage of the old wood should be removed together with any weak growth, and development of new shoots encouraged by mulching with compost or animal manure. *Prop.*—Cuttings rooted in sandy soil under a hand light in summer; suckers thinned out in winter.

Stocks.—*See* Mathiola.

Sunflower.—*See* Helianthus.

Sweet William.—*See* Dianthus.

Symphoricarpos (Snowberry).—Often found existing in deep shade and in competition with roots of overhanging trees, presumably as a result of the generalisation that the shrub is a shade lover. Certainly a useful one in this respect, but it is responsive to good treatment. Given an average soil and if growth is thinned annually in the early spring, then *S. albus* 'Laevigatus' is well worth having. Its large white fruits are untouched by birds and hang well into the winter, and are thus beloved by the floral decorator. *Prop.*—Suckers removed in the winter.

Syringa (Lilac).—The botanical name of *Syringa* is often erroneously applied to the Mock Orange, correctly named *Philadelphus* (*q.v.*). A wide selection of first-class varieties are available in nurserymen's lists. To obtain heavy crops of flowers nip off all dead flower-heads as the blossom fades, but do *not* cut back into the old stem, as this will prevent flowering. At the same time any branches causing overcrowding can be removed. Annually feed with "National Growmore" at 2 oz. per sq. yd. and on sandy soils mulch with any sort of manure or compost. *Prop.*—Layering in the autumn.

Tagetes (African and French Marigolds).—Half-hardy annuals of free-flowering habit and easiest culture. Best if fed generously with soot water or other nitrogenous manure during growing season. *See* Annuals.

Tropaeolum.—The common nasturtium and the flame flower (*T. speciosum*) belong to this genus. The former is easily grown from seed sown in May in a sunny position. The latter is a very difficult plant to grow outside the conditions which it demands. To be successful, this perennial climber must be planted in acid soil which is naturally damp and lightly shaded but yet where the new growth can reach full sun. Much disappointment often results from planting it in eastern England, for instance, after seeing it flourishing almost as a weed where the rainfall is high in Ireland and the west of Scotland.

In the genus will also be found the canary creeper, which can be used for screening purposes and will thrive in full sun or shade. Seed is sown in May in open ground and light supports supplied by way of pea sticks or strings; failure is normally due to nothing more than lack of moisture.

Tulipa (Tulip).—Thrives in a deep, rich loam, but will do well for one season in ordinary garden soil. When used for bedding, bulbs must be lifted after flowering, replanted in a trench, and thoroughly watered. Sometimes tulips may be left in the ground if conditions are favourable, and then the stock only needs lifting and replanting every three years. To check the incidence of tulip fire plant in late November or early December, covering the bulbs with 4–5 in. of soil and treat the ground with a fungicide like "Botrilex." Before doing so rake in a dressing of 2 oz. superphosphate and 1 oz. sulphate of potash per square yard. A national collection of wild tulips is being got together at Cambridge and grown there in the University Botanic Garden.

Viola.—This name embraces pansies, violas, and violets. Although the viola has not got the rich colours of the pansy (or its attractive markings), it has got a remarkably long season of flower, and for this reason it is invaluable as an edging plant or as ground cover for roses. *Prop.*—Both plants are easily raised from seed sown in a frame in the spring, pricked out, and then transferred to their flowering positions in late May. Alternatively, seed may be sown in July for planting out in October. Named varieties increased by cuttings in a frame in late summer.

Virginia creeper.—*See* Parthenocissus.

Wallflower.—*See* Cheirianthus.

Water Lily.—*See* Nymphaea.

Winter Sweet.—*See* Chimonanthus.

Wistaria.—One of the finest of all climbing plants for south or west walls or stout pergolas. Plants which do not flower, or only do so poorly, are probably seedlings and the true flowering habit cannot be induced; the only solution is to replace with a *grafted* plant of known flowering capacity from a reliable nurseryman. All young shoots not required for the extension of branches should be shortened to within 3 in. of the old stem in the

autumn. Wistarias growing over trees do not require pruning. *Prop.*—Layer shoots of current season's growth in the autumn.

Zinnia.—Half-hardy annual, ideally grown on moist, deep loam liberally enriched with well-decayed manure. Mulch with manure after planting and apply liquid fertiliser as buds appear; plants must not suffer from lack of water. *See* Annuals.

MAKING A LAWN.

In almost every garden the most prominent feature is the lawn, and often a lot of work is put into making one without any great measure of success. Usually, the reason for failure may be found in faulty preparation of the soil or premature sowing, albeit the blame is often placed on bird damage or poor seed.

For anything like a reasonable turf, the site must be thoroughly dug and the content of organic matter increased by incorporating generous quantities of materials like peat, leaf-mould, compost, sewage sludge, and animal manure. A dressing of these ingredients can be applied in a layer 3–4 in. thick and buried in the bottom of the top spit of soil. As the ground is dug to incorporate the organic matter, roots of perennial weeds should be removed.

If the site is one on which water tends to lie or if the soil is heavy, then surface drainage should be sharpened by forking into the top 2 or 3 in. a liberal application of some coarse material such as builders' rubble, road grit, screened ashes, or coarse sand. In some cases this treatment will not be sufficient, and then the installation of land drains must be resorted to. This particular task is not as difficult as is sometimes imagined, but, before a start is made, it is always a good plan to discuss the matter with an experienced man.

After the initial work a fine tilth on the soil may be obtained by thoroughly raking and cross-raking and at the same time establishing a level surface. On this point, it should be remembered that good lawns can be made on undulating ground or on natural slopes, but the things to avoid are the shallow depressions where water will naturally tend to lie. Finally, ten to fourteen days before sowing the subsequent growth of grass can be encouraged by making an application of "National Growmore" at 2 oz. per sq. yd.

Sowing is best done in the late summer at a time when the soil is moist For the purpose, a good mixture of seed should be obtained from a reliable seedsman, and it is worth paying a reasonable price for it, as, by and large, the coarsest and roughest grasses have the largest and heaviest seeds. Opinions differ on rates of sowing, but, with care and in a well-prepared soil, 1 oz. per sq. yd. is ample; heavier rates will give quicker results, but the density of seedlings in such cases often leads to the finer grasses being choked by the coarser ones.

After sowing, the ground should be lightly raked, but not rolled. At this stage the important point is to protect the seed bed from birds by the use of hazel sticks, strings of papers tied to stakes after they have been dipped in lime-wash, and strands of black cotton. Subsequently, annual weeds may appear in quantity; these are of no consequence, and they will be eliminated once the grass is cut regularly. Until a good turf is formed —usually about twelve months after sowing—it is not desirable (or probably necessary) to use hormone weed-killers. *See* T33.

Care of Established Lawns.

Most turf is never manured from year to year, and the soil may seriously lack plant foods. In the first place this can be corrected by making an application annually in the spring of "National Growmore" at 1 oz. per sq. yd. Following this, if growth is below par in the early part of the year an application of sulphate of ammonia can be made at the same rate. To avoid scorching or blackening of the foliage, each fertiliser can be mixed with equal parts of dry soil or sand as a carrier to ensure even distribution and, what is most important, each one should be applied only when the turf is wet and there is the prospect of rain to follow. Linked with this treatment, turf is always responsive to top dressings. A compost for the purpose can be made up with:

2 parts of loam;
1 part of sieved compost;
1 part of fine peat or leaf soil.

This may be used in the spring at 3–5 lb. per sq. yd. and if the soil is heavy 1–2 parts of gritty sand may be added.

With the introduction of new designs in motor mowers, most lawns are seriously overcut, and this has led to a sharp decline in the quality of the grass and the appearance of one or two pernicious weeds. Special turf, such as that found on a bowling green, may be shaved off to one-sixteenth of an inch, but if a utility lawn is cut below half to one inch then the quality of the grass will deteriorate. Of course, it is a good thing to occasionally cut the grass very short, but, conversely, if the blades of the mower are set as low as possible and left like it throughout the season nothing but harm can result. The reason for this hard fact is that when the turf is cut very close the grasses simply cannot develop and spread, and weeds will gradually establish themselves. Eventually the cultivator will be faced with the difficult problem of trying to deal with such plants as pearlwort, yarrow, and various mosses, all of which are resistant to hormones.

As for the vexed question of whether or not to remove the mowings, there is no doubt that the best turf is found where the mowings are collected up, although in very dry weather they can be left on the surface. If the clippings are not removed the surface of the turf tends to become choked with semi-decayed organic matter, and conditions are brought about which are inducive to the spread of moss.

Finally, it is worth noting that the finest turf is found on acidic—not alkaline—soils. For this reason, lime should not be applied as a general rule, for apart from helping the development of coarse grasses, it encourages the growth of clover. Of course, there are times when lime is necessary, but the occasions are rare and before it is used it is a good plan to test the soil by chemical means.

THE FRUIT GARDEN.

The guidance of an expert is probably more important in the growing of fruit than for most of the commoner vegetables and ornamentals. This is primarily because the majority of fruit trees and bushes are long-lived, and only in the case of strawberries can a change of site or variety be made easily and inexpensively.

Gardens which are low-lying are very prone to damage from spring frosts, and should not have too much space devoted to fruit, as returns may well prove unprofitable. Here, as with the selection of varieties, advice of a local expert is invaluable. Some varieties do better in certain localities and on certain soils than others, although personal preferences will naturally be met where possible. Varieties chosen should cover as long a season as is practicable so that the fruit can be used and enjoyed to the full.

Tree fruits are grown on a rootstock, and for apples and pears special dwarfing stocks make these a possibility for the small garden. It is therefore important to explain to the nurseryman what type of tree is required. As a general rule, however, the smaller gardens will gain by concentrating on currants, gooseberries, raspberries, and strawberries. Plums and cherries have no

dwarfing stocks, and should be included only where sufficient room is available.

Apples.—Can be grown on most soils. Manure should not be used when planting, except in sandy and chalky gardens. Obtain trees on dwarfing rootstocks, such as M.IX, M.VII, or MM.106. Always stake trees on M.IX, otherwise this practice is necessary only in exposed sites. The tie must be rigid, with a "cushion" between tree and stake to avoid chafing, and must be renewed annually to avoid constriction. Plant between late October and early March, preferably before Christmas if soil and weather allow. Make the hole large enough to spread the roots evenly; firm thoroughly while filling in and plant level with the nursery soil mark already on the tree. Mulch around each tree with manure or compost, mainly to avoid drying out, and supplement with watering during the summer when necessary.

In the first year any flowers produced are best pinched out to encourage root and shoot development. For walls or fences use oblique cordons or espaliers; these are also useful for flanking paths and lawns. Plant cordons 2½ ft. apart with 6 ft. between rows, and espaliers 12–15 ft. apart. For larger areas use bush trees 12–15 ft. apart.

Manuring for cropping trees should be varied according to growth. Generally apply 1 oz. sulphate of ammonia (or nitro chalk on acid soils) in early March, repeating this in early April if trees are growing in grass. Give ½ oz. sulphate of potash in February and add 3 oz. of superphosphate every third year. The above rates are per square yard, and a complete fertiliser can be used in lieu if preferred.

Young bush trees should have main shoots reduced by half in early years to produce strong branches. Thereafter prune side shoots to three to six buds. For weak growers prune harder, and for strong growers prune less. It is wiser to leave a strong tree unpruned than to prune it too severely, the latter merely encouraging even stronger growth. A few varieties (*e.g.*, 'Bramley's Seedling,' 'Worcester Pearmain') fruit at shoot tips, and here a proportion of side shoots should be left unpruned. Summer pruning is advisable on restricted trees, such as cordons; for details see **Pears (T17)**.

Very few varieties are self-fertile, and at least two sorts should be planted to ensure satisfactory crops. Good combinations are 'Cox's Orange Pippin' with 'Laxton's Fortune' and 'Winston' with the cooker 'Lord Derby.' Seek expert advice on pairings if in doubt. Some discerning housewives like apples which break down or fluff on cooking; in this case 'Emneth Early,' 'Lane's Prince Albert' or 'Monarch' may be planted. For those wanting one which stays firm on cooking 'Bramley's Seedling' should be chosen.

Blackberries.—In modern gardens, where space is limited, the best returns in fruit growing are often with the cultivated forms of blackberries and loganberries. Plant at least 10–12 ft. apart against fences and train on wires set 3 ft., 5 ft. and 6 ft. above soil level.

Cropping is dependent on manurial treatment as all are heavy feeders. When planting enrich the site with manure, compost or leafsoil; afterwards mulch the surface with one of them. Annually the ground should be topdressed with compost supplemented with a nitrogenous manure like sulphate of ammonia, chicken manure or dried blood. Also apply sulphate of potash at 1 oz. per sq. yard. Such treatment will show excellent results and, as a bonus, normally ensures a prize at any local Show. After planting, do not lack courage to cut back all growths to within a foot of ground level and keep the soil moist throughout the growing season.

Cherries.—Sweet cherries are unsuited to most gardens. The trees become too large, and *must* be planted in selected pairs to fruit satisfactorily, as all varieties are self-sterile. Large wall spaces are ideal for fan trees, as the fruit can then be protected from birds by the use of nets. Pinch side shoots on fans to four leaves in July; further pruning details being as for plums. Expert advice is essential to ensure that suitable varieties are grown together the factors involved being complicated. 'Early Rivers' with 'Bigarreau Schrecken' and 'Merton Heart' with 'Waterloo' are good combinations.

Currants, Black.—These are perhaps the most valuable of all hardy fruits, and bushes will give up to 10 lb. and more of currants with correct treatment. Plant from November to February, preferably autumn, at 5 ft. square on clean, heavily manured ground. In the following spring it is important to cut *all* the shoots to within 3 ins. of ground level in order to encourage strong new growth.

Poor results with this fruit are often due to keeping old or worn out bushes when the cropping life is past which, for blackcurrants is around 10 years. Another reason is the lack of feeding. Each spring bushes should be mulched with compost supplemented with a nitrogenous fertilizer like sulphate of ammonia at 1 oz per sq. yard and superphosphate at double this rate.'

On established bushes prune preferably after fruiting or in winter, retaining strong young wood and cutting out older shoots, where possible from ground level. If necessary, alternate bushes can be cut down completely every other year to maintain vigour, as the bulk of the crop is always borne on young wood. Increae by 8-in. cuttings of one-year-old wood taken in late September from healthy bushes. Remove lower leaves and insert firmly with one bud above ground. Good varieties: 'Boskoop Giant,' 'Wellington XXX.'

Currants, Red and White.—One or two well-grown bushes are usually sufficient for the average household. Plant between November and March at a minimum of 5 ft. square on well-manured ground and mulch each spring. Supplement with fertilisers if necessary, potash being particularly important in the form of sulphate of potash at 1 oz. per sq. yd. in February. Can be grown as cordons or fans against walls or fences, on which the pinching of young side shoots to four leaves in mid-June is essential. Winter pruning of all types simply involves cutting side shoots to one bud and tip pruning branch leaders.

Propagate by 12-in. cuttings of young shoots in late September inserted to half their length with all buds removed except the top four. This enables the bush to be grown on a "leg" A permanent framework of branches is then developed, as, in contrast to the black currant, fruit is borne on spurs on the old wood. Good varieties: 'Laxton's No. 1,' 'White Grape.'

Damson.—*See* Plums.

Figs.—A warm south wall is usually essential, 'Brown Turkey' being one of the few reliable outdoor varieties. Plant in a brick or concrete trough (with drainage holes) about 2½ ft. wide, 5 ft. long, and 2½ ft. deep so that the root run is restricted. This will curb excessive growth (which otherwise is difficult to control) and encourage fruiting.

Plant in March for preference, to avoid frost injury to young shoots, and then train fan-wise. A rich soil is not essential. Figs visible as such in the autumn will never over-winter, and should be rubbed out. Those the size of a pea and less at the tips of short, well-ripened shoots, on the other hand, are the potential crop for the following year, and should be covered in severe weather to avoid frost damage. To encourage the formation of these embryo fruits pinch young shoots back to the fifth leaf in late August. Winter prune in March, removing any wood that is frosted, overcrowded, or worn out; growths should be spaced at about 1 ft. Apply a spring mulch and water freely when required to avoid premature fruit drop.

Gooseberries.—Need conditions and spacing very similar to red currants, but with rather more moisture to ensure ample new wood, as this bears fruit as well as the older wood. Apply sulphate of ammonia and sulphate of potash annually in late February or March at 1 oz. per sq. yd. of each in addition to mulching. Can also be grown as cordons, etc., as for red currants. Pruning is also similar, though not quite so severe, as the young wood is productive of fruit. Cuttings are more difficult to root, and 10 best results should

be taken in mid-September, again as for red currants. Good varieties: 'Lancer,' 'Leveller,' 'Whinham's Industry.

Grapes.—Outdoor vines should be grown against a warm south- or south-west-facing wall. With good cultivation, the grapes should then ripen successfully providing suitable varieties are chosen. In preparing the site ensure that it is well drained and break up the soil to a depth of about 2 ft. Add bone meal to the top few inches at 3–4 oz. per sq. yd. and incorporate mortar rubble, particularly on the heavier soils. Do not dig in any manure except on poor, light soils, but always apply some as a mulch after planting, repeating this every spring. On poor, hungry soils the importation of some fibrous loam is advisable where possible.

Plant in November or, failing this, before early March, with the stem about 6–9 in. away from the wall. Firm well and then wait a further two months before tying to any wires or stakes, in case of soil sinkage. Cut the vine back in winter to well-ripened wood and to just above a bud. The training of subsequent growth will then depend on the space available, single and double cordons being the most convenient. Unwanted shoots should be pinched at about 2 ft. in summer and leading shoots carefully tied in to wire or bamboo supports. The following winter (December) prune leading shoots back to well-ripened wood so as to leave 3–4 ft. of new growth. Then cut all laterals hard back to *one* bud. In spring reduce young side shoots to one at each bud, stop laterals at about 12 in., and pinch any sub-laterals that may develop to the first leaf. Do not allow any crop to develop, except perhaps one bunch if growth is adequate; others should be pinched off. As fruit develops, thinning should be done as required. Winter prune as before, and then in the third summer four or five bunches of grapes can be allowed if the vine is healthy, the crop then increasing annually. Shoots carrying bunches should be pinched to two leaves beyond the bunch. Winter pruning is repeated each year as already described. Sour top-soil should be carefully removed when necessary and replaced with good loam while the vine is dormant. Good varieties: 'Black Hamburgh' and 'Foster's Seedling.'

Loganberries.—A very popular hybrid berry which should be treated as for blackberries. A thornless form is now available. Suitable for a north wall.

Medlars.—A tree of spreading habit, the peculiar fruits of which are best used for jelly before they are fully ripened. Most soils are suitable, and no pruning is needed except to keep in shape.

Nectarines.—A fruit very closely allied to the peach but with a richer flavour and needing rather more warmth. The skin is smooth, as distinct from the hairiness of the peach. For full details see Peach.

Nuts.—The most important kinds grown are cobnuts, the closely related filberts, and walnuts, but none of these is cultivated to any great extent. The two former kinds flower very early in February, and are therefore predisposed to frost damage; similarly, the young shoots of walnuts are easily injured by spring frosts, and all are therefore inadvisable for frosty areas.

Cobnuts and filberts.—Highly developed forms of the ordinary hazel nut. The nut of a cob is only partially covered by the husk, whereas a filbert is completely enclosed by it, this being the essential difference between the two. Will grow on most soils, including the poorer ones, and spacing should be about 15 ft., choosing sites sheltered from the colder winds. Plant during the autumn. Prune established bushes in March, cutting back shoots that have borne nuts to two or three buds; strong young shoots are cut back to a catkin near their base, and the weaker ones are left untouched. In August any strong new side growths are "brutted"—that is, broken off—and left hanging until the March pruning. Gather the nuts as they fall and allow to dry. Then store in jars for Christmas use, packing salt and coconut fibre between each layer of nuts.

Walnuts.—Special, grafted varieties are now available which produce early crops compared with the unreliable seedling trees that used to be planted. Plant between October and March and water well in spring and summer. Do not prune, as walnuts bleed badly. Gather nuts in mid-July for pickling. For storing allow to drop naturally and remove outer husk immediately, scrubbing the shell clean and then drying thoroughly. The shells can be bleached if necessary before storing the nuts as for cobs above.

Peaches.—This fruit along with its close ally, the nectarine, is best grown against a warm south or south-west wall, but two varieties of peach, 'Peregrine' and more particularly 'Rochester,' will succeed as bushes in the open in southern England. The fan-trained peach is one of the most difficult trees to keep in order, as sufficient new shoots must be retained annually to replace old wood. This is essential, as it is only the previous year's shoots which bear fruit. Badly placed shoots are rubbed out when only an inch long, and the principle is to allow one young replacement shoot to develop near the base of each fruiting shoot, pruning back to the former and tying it in as soon as all fruit has been picked. Other shoots may be used to extend the fan where space allows or to replace any branches or parts of them which may have become worn out. Other unwanted shoots are bound to arise during each summer, and these are either removed immediately or pinched to three leaves and then removed when pruning in late summer. Those shoots retained are spaced at about 4 in. apart.

Most peaches are self-fertile, but hand-pollinating on sunny days can improve the set. Excessive feeding should be avoided, varying this according to each tree's performance, but as a general rule a surface mulch of well-rotted manure or compost should always be given each spring, together with sulphate of potash at ½–1 oz. per sq. yd. Prick over and rake off top-soil and replace with good loam every few years. Never allow the sub-soil to dry out—this can quickly occur against warm walls—and water thoroughly when doing so to ensure an even distribution of moisture. On the other hand, drainage must be satisfactory to avoid waterlogging.

There are numerous other essential operations in the growing of trained peach trees (for example, fruit thinning), and it is impossible to deal with these adequately in brief notes. Would-be growers should therefore seek expert advice and obtain literature dealing specifically with the crop rather than risk disappointment. Good varieties for outside wall training include: *Peaches:* 'Peregrine,' 'Bellegarde.' *Nectarines:* 'Early Rivers,' 'Lord Napier.'

Pears.—The requirements for pears are similar to those for apples, but the necessity for adequate summer and autumn warmth rules out many varieties for northern areas. In these less-favoured localities enquire which varieites do succeed, and where possible make use of a warm, south-facing wall. Protection from wind is very important, particularly from the cold easterlies of spring. Many soil types grow pears satisfactorily, providing drainage is good and the trees are looked after. Plant as for apples. Fertiliser requirements are also similar once cropping commences, except that pears may require a little more nitrogen.

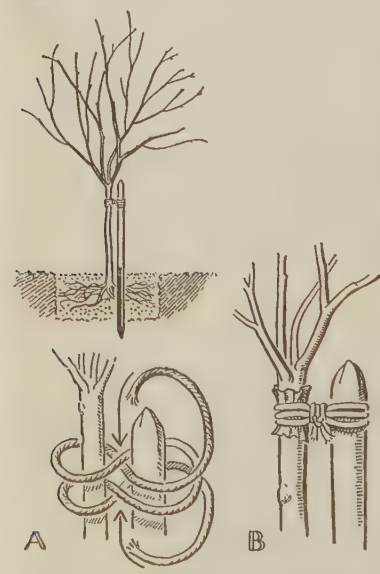
Pruning (winter) is comparatively simple, the spur pruning given for apples suiting all except a very few pears. Initial shaping is essential, cutting the stronger shoots selected to form branches by about half their length and keeping the centre of the tree open. For cordons and other restricted forms of tree, to which pears lend themselves particularly well, summer pruning is advisable. This involves shortening all young shoots more than 10 in. in length to about 5 in. from the base. Do this when the base of such shoots is hardening and turning brown in colour, usually late July–early August. Pruned shoots may then be further reduced in winter. Such summer treatment may also be given to trained apple trees with advantage during August.

Only a few pears are self-fertile and 'Con-

ference' is the most reliable if only one tree can be planted. Good pollinating pairings include 'Laxton's Superb' with 'Doyenné du Comice' and 'Conference' with 'Williams' Bon Chrétien.' Early varieties should be picked a little before ripening and used quickly.

Plums.—This general term includes gages and damsons. Numerous varieties are easy to grow but are unsuited to small gardens because of the amount of space required. Unlike apples and pears, there are no dwarfing rootstocks, and a minimum spacing of 14 ft. should be allowed for, growing the trees as half standards, or fan-trained against a south or west wall. Flowering is during April, and frost damage can be serious in some seasons. Plant preferably in the autumn, and by early March at the latest, using no manure unless soil is distinctly poor. Young trees should be staked during their early years, and must not be allowed to rub against the support.

Pruning should be reduced to a minimum, as the spores of silver leaf disease gain entry through wounds such as pruning cuts and stake rubs. Shorten branch leaders on young trees just as buds are bursting, but on older trees prune only when branches become overcrowded. Do this between June and August, when the risk of silver leaf is at a minimum. Cut cleanly and coat the wounds thoroughly with a bituminous paint; treat broken branches similarly immediately they are noticed. Trees fruiting heavily should have the branches supported and the fruit thinned in late June. Side shoots on fans must be cut to four to five leaves in late June and reduced still further following picking if necessary. Feed cropping trees regularly to encourage new growth, by mulching the soil generously with manure, compost, or leafmould in early spring. Some varieties are self-fertile, including 'Victoria,' 'Oullin's Golden Gage,' and 'Merryweather Damson.'



A WELL-PLANTED TREE, illustrating (A) a good method of tying and (B) sapling firmly secured with sacking around the trunk and held with stout cord.

Raspberries.—These are an ideal fruit for the small garden, but because of virus disease always buy certified canes from a fruit nursery. Plant between November and March on clean, well-manured ground, allowing 18 in. between canes and 6 ft. between rows. After planting prune each cane back to 12 in. Do *not* attempt to crop them in their first year, or the production of young canes for the following year's fruit will suffer.

A semi-shaded position will answer, but full sun is preferable for quality fruit. New canes should be looped with string to a post-and-wire fence and later tied individually to each wire when fully hardened. Space them at about 4 in. and remove any weak or diseased canes at ground level. In late February cut each cane to just above the top wire, which is usually 5–6 ft. high. This removes any damaged tips and may encourage fruiting over a longer length of cane. In the second summer a fair crop should result, and netting against birds is essential. Regular watering is imperative in dry weather, and spring and summer mulches of well-rotted manure or compost should always be applied. Supplement this in March with nitrogen and potash (fertilisers) if required, this depending on how well the ground was manured before planting. After fruiting cut out all old canes and tie in the new ones as already described. 'Malling Promise' and 'Lloyd George' are good varieties.

For autumn-fruiting varieties prune all canes to the ground in late February and tie in the best during the summer for cropping in September–October. 'September' is a good variety, and 'Lloyd George' can also be used.

Strawberries.—This is the one fruit that should be included in the vegetable garden. Fresh ground can then be used regularly for establishing new beds. Plants more than two years old are seldom profitable, and the best fruit is always picked from healthy one-year-olds planted the previous August or September. Runners put in later than early October should be deblossomed the following spring, the reward being a much heavier crop in the second year. This wastes ground, however, and early planting is preferable on all counts. Prepare the ground well in advance of planting and dig in plenty of well-rotted manure or compost or both, as this is the key to success.

Because of virus diseases order certified plants from a fruit nursery and burn any unhealthy ones in old beds before planting. Insert firmly with the base of the crown of each plant just at soil level and refirm after winter frosts; space at 20 in. in rows and 2 ft. 6 in. between rows (3 ft. if possible). A mulch of rotted manure or compost is beneficial each autumn, together with an application of sulphate of potash at 1 oz. per sq. yd. In the spring growth can be encouraged by feeling with "Maxicrop"; quick-acting *nitrogenous* fertilisers should normally be avoided.

During flowering cover the plants where possible to guard against frost damage reducing the crop. Keep the ground weed-free and remove runners regularly; a few plants should always be grown away from the main bed, deblossomed and kept purely for runner production, as this then helps to reduce the spread of virus. Ruthlessly burn any plant that remains stunted, including its runners, as this is usually a symptom of virus disease. When the young fruits are just forming spread clean straw underneath them to avoid splashing from the soil; it is a mistake to do this too early, as it increases the risk of frost damage. Net the fruit against birds and remove any rotting specimens when picking.

After fruiting remove and burn all old foliage, weeds, and straw, and feed as already described. Plant a percentage of new, vigorous runners each year on fresh ground, at the same time burning the old ones they are replacing. For flavour, the best variety is still 'Royal Sovereign' of which healthy stocks are available.

Alpine strawberries require similar treatment, preferably with a semi-shaded position, and should be raised from seed. Perpetual fruiting types continue fruiting on and off well into the autumn, and should be treated as for ordinary varieties. In all cases cloches can be used from late February onwards to obtain early fruit.

THE VEGETABLE GARDEN.

The Small Plot.—For some years the trend in gardening has been decidedly towards growing ornamental plants; vegetables have been neglected. This has gone so far that in many instances the vegetable plot has been done away with altogether. As a result, throughout the summer housewives have faced the high cost of buying even such easily grown crops as lettuce or going without them when supplies are short. A further factor promoting a return to home gardening has been the information now available on the toxic properties of some chemicals used freely in commercial horticulture.

To avoid these problems, even a small piece of ground can be used to excellent purpose if first manured and dug over thoroughly. The ideal site is an open, sunny position, sheltered from cold winds with the soil a deep rich loam well supplied with humus; obviously few gardens have such a site but much can be done in most circumstances. Once the ground is ready a few sowings of radishes can be made and lettuce cropped throughout the summer. Other vegetables worthy of consideration are the sowing of spinach and onions grown from sets. Of course, in the small plot, priority should be given to providing a fresh supply of herbs like sage, thyme, chives, parsley and a clump or two of rhubarb.

General Cultivation.—On a new site soil preparation is important as all vegetables do best on ground in good heart. The land should be dug two spits deep (" double digging ") and for this purpose the plot is divided into two longitudinally and a trench 2 ft. wide and 10 in. deep is dug out, as illustrated above. The sub-soil at the bottom of the trench is then broken up and manure or compost added (or turf if grassland is being dug). The next strip is then dealt with in a similar manner and the practice continued down the plot to the last trench which is finally filled in with the loose soil from the first trench. Double digging is not necessary every year and single digging carried out in a similar way without breaking up the second spit, or sometimes a light forking over is sufficient.

Clay soils can be lightened by adding heavy dressings of peat or compost and coarse materials like ashes and road grit. Sandy soils are also improved by addition of humus, in this case to conserve moisture . These soils are less fertile than clay ones but are easier to cultivate, are warmer, and crop earlier. In both cases the addition of lime is only desirable if the ground is too acid; most vegetables, it should be noted, do best on slightly acidic soils *not* alkaline ones. If any doubt exists then it is always best *not* to lime.

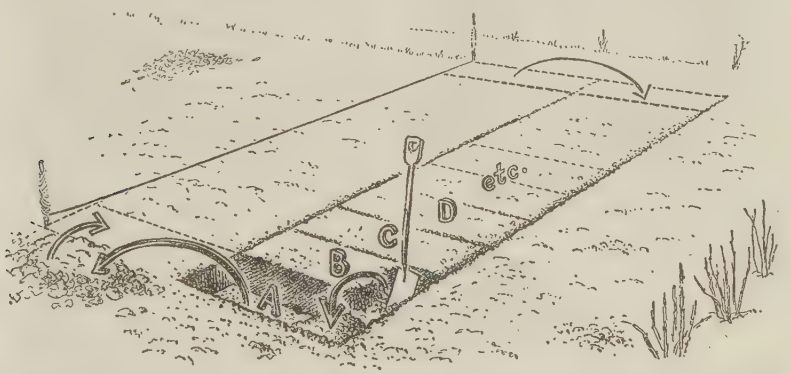
The lay-out with vegetables must be designed to provide a succession through the year and to utilise the full capacity of the ground by catch crops and a suitable succession. The land can be divided into four plots; one is used for the more or less permanent crops, such as asparagus, rhubarb, and globe artichokes, and the other three will provide a rotation. This is used to stop any group of vegetables being grown on the same land more than once in every three years, so preventing the carry-over of some pests and diseases and providing for a full use of the manures in the soil, as different groups of vegetables need more of some nutrients than others. It also allows the clearance of one section to enable winter digging and manuring to be carried out. On this freshly manured plot peas, beans, onions, leeks, and lettuces, all revelling in rich ground, should be grown. The next plot, manured for the *previous* crop, can be used for root crops—early potatoes, carrots, parsnips, and beet. A light dressing of artificial fertiliser such as " National Growmore " should be applied before sowing. On the third plot the green vegetables should be grown; a dressing of fertilisers is desirable, and lime should also be applied.

In the following season the root crops can be grown on the plot which was manured the previous year, and the brassicas grown on the land vacated by the root crops. The plot on which the brassicas were growing is double dug and manured ready for the peas, beans, and onions. A system of this type proves very satisfactory, but numerous variations can be devised, and it is really a matter for the gardener to decide his best method. The growing of maincrop potatoes will complicate the system, as a large area is usually required. They are better grown separately in another part of the vegetable garden.

Usually it is wise to have a small piece of ground available for a nursery bed. This should be of good, fine soil in which seeds can be sown to supply the main plot. In all cases seed should be sown very thinly to prevent the necessity for much pricking out, and a slug-killer is often a wise precaution to use before sowing. Sowing dates, as given, are mainly for growers in the South. In the North sowing dates in spring will be generally two weeks or more later and autumn operations the same amount earlier. Any gardener must adjust his work to suit local conditions of soil and climate, and this knowledge is only gained by experience of the particular area.

General cleanliness in the vegetable garden is at all times desirable; weeds and rubbish only harbour pests and diseases, and the hoe should be busy whenever possible. Waste material can be utilised in that essential of the modern garden—the compost heap. *See* **Manures** and **Fertilisers** for description.

Frames and Cloches.—The gardener is able to extend the season of many crops by protecting them under frames and cloches; this is particu-



DOUBLE DIGGING—A sound cultural practice. A trench 2 ft. wide and the depth of a spade is taken out at A and placed as shown. The bottom of trench A is then forked up and filled in with soil from B and the process repeated with C and D, etc. In double digging the sub-soil is *always* left on the bottom and never brought to the surface.

larly useful where spring or early autumn frosts are prevalent. The use of frames is limited, as they are in a fixed position, but nevertheless they are very useful for obtaining out-of-season salad crops, especially if they are heated by electricity or a hot bed.

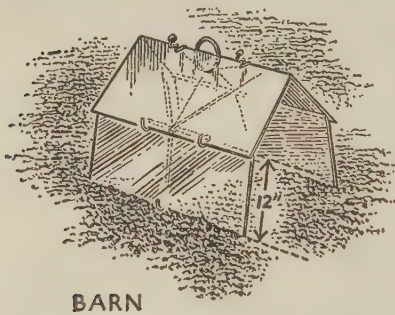
Cloches have the advantage of mobility and can be used on a number of crops in succession. Essentially, each is a number of pieces of glass in a tent or barn shape held together by wire. Pattern, size, and height vary according to the crop to be covered and the manufacturer's design. A good cloche should be of simple design, rigid and capable of standing up to ordinary winds, easily transported, and well ventilated.

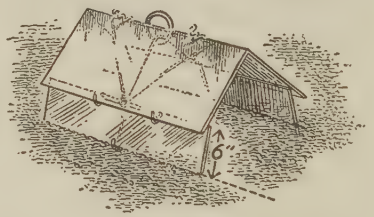
The low barn cloche is probably the most economical type. This is 23 in. wide and 13 in. high when erected, and will allow two rows of lettuce to be grown, with an intercrop of another vegetable. The large barn or barn cloche of similar design, but with 12-in. side is 19 in. high in the centre, enabling taller crops, *e.g.*, peas and dwarf beans, to be grown on, almost to maturity. The tomato cloche has sides 24 in. square and a basal width of 26 in. Many others of various shapes and sizes are offered; the amateur should buy to suit his own requirements. Other materials have been tried instead of glass with varying success. Plastic cloches are on the market, but their lightness entails very safe anchoring, and at the moment glass still seems to be the best material in most instances.

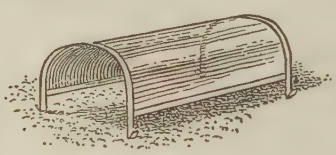
Gardening under cloches obviously is a subject too large to be dealt with in a few sentences, and the reader would be well advised to refer to one of the books mentioned in the bibliography for fuller information. A few of the main points are mentioned here and also under the individual crops.

Cloche cultivation is an intensive method of production, and this means that the land must be well cultivated and manured to ensure good-quality crops at all times. About ten days before crops are sown or planted the cloches should be put in the position where they are to be used, to warm the soil. The crop is sometimes sown a month before the normal date, and this prewarming ensures that the soil can be cultivated to a good tilth, as well as giving the plants a good start. Watering is a problem that often bothers the amateur. Provided the soil is well watered at sowing time, there should be no need to decloche to water. Rain seeping under the cloches and a spray directed over them occasionally will provide enough for the crop in normal weather; on dry, sandy soils it may be necessary to spray over the cloches more often. A mulch of compost is also very useful to help retain water.

Dwarf varieties should be used for growing under cloches, although methods of raising the cloches another foot or so have been devised and are on the market, which allow the use of taller growing varieties. Many different vegetables can be helped to some extent in the early stages, besides those crops which can be grown entirely under cloches; the grower must decide what crops he needs and ăt a rotation to cover as many crops as possible with the cloches available. This is mainly a matter of experience, but books on the subject will suggest many variations that can be tried. Intercropping with quick-maturing crops can also be practised. As instances, radish or mustard and cress can be cropped between two rows of lettuce, or a row of cos lettuce can be grown between two rows of cabbage lettuce.







TYPES OF CLOCHES—The most popular is the barn cloche; with 12-in. sides it will cover strawberries and peas and beans in their early stages. The low barn will accommodate three rows of lettuce in winter and cucumbers in the summer. Plastic cloches are growing in popularity, especially those patterns using toughened plastic, and have some decided advantages over glass ones.

It must be remembered that the glass of cloches will need cleaning from time to time; the crop still needs the maximum light available, although shading of certain crops may be necessary in hot sun.

Artichokes.—Two different plants are grown as artichokes. One, the Jerusalem artichoke (*Helianthus tuberosus*), is related to the sunflower and is grown for its tuberous roots, which are second in food value only to the potato. It will grow in poor soil, but amply repays good cultivation, and may be placed at the more exposed end of the vegetable plot as a windbreak and screen. Tubers should be planted during February or March, on well-manured ground in drills 4–6 in. deep, and 2 ft. 6 in. apart, with 15 in. between the tubers. Hoe frequently during the summer and cut the stalks down in early winter. The tubers may then be lifted and stored, or better dug as required, reserving a number for replanting the following February.

The other type, the globe artichoke (*Cynara scolymus*), is often grown as an ornamental plant, but is esteemed as a vegetable for its young, fleshy flower-heads, which must be cut before the scales begin to open, after which they become hard and unpalatable. A deep, rich, well-manured soil is

required, and after planting in early spring in rows 4 ft. apart, with 2 ft. between the plants, a compost or manure mulch is beneficial. A good crop may be expected for five or six years provided an annual dressing of manure is applied. After this time they should be replaced by young suckrse. planted in a fresh position. A covering of straw or bracken on the crowns is advisable during winter.

Asparagus.—This will grow on most types of soil provided that drainage is good and that plenty of organic matter is available. The site for the asparagus bed should be double dug in the autumn prior to planting, and a generous dressing of about half a barrow load of manure per square yard incorporated. Crowns up to three years old may be bought, but it is found that one-year-old crowns give the best results. Plants may be obtained cheaply by sowing seed in late March in drills 1½ in. deep and 18 in. apart and thinning the seedlings to 4 in. apart. It is thought that male plants produce more stalks of better quality than female plants, but at present no supplies of male crowns alone are available.

Planting may be on the single-row system or the wide-bed system. In the single-row system crowns are planted 18 in. apart in rows 4½ ft. apart; the wide-bed system consists of 5-ft. beds, with three rows of crowns 15 in. apart each way, and 2 ft. between each bed. Planting is best done during April and the plants are placed in a trench 8 in. deep and 1 ft. wide, with a slight ridge at the base, and covered with 3 in. of soil. The remaining soil is worked in during the summer. The roots should never be allowed to dry out.

The following March 2 oz. per sq. yd. of sulphate of ammonia should be applied; in subsequent years 3 oz. per sq. yd. of "National Growmore" applied at the same time, followed by 2 oz. per sq. yd. of sulphate of ammonia in June, after cutting, can be used. Salt, as a fertiliser, is not recommended nowadays. An annual dressing of manure or compost in November is desirable.

No cutting should be done for the first two years after planting and only a light cut taken in the third year. After this a six-to-eight-week season beginning in early May is usual. The spears should be cut when about 4 in. above soil level and severed about 2 or 3 in. below the soil, giving an overall length of 6–7 in. The fronds should be cut in October before the seeds drop, but not during the summer, as the plant is weakened. Weeds should be kept down and in the autumn the plant may be earthed up.

Varieties: 'Connover's Colossal' and 'Kidner's Pedigree.'

Beans. Three types are commonly grown, as follows:

Broad Beans are the hardiest and can, in warm gardens, be sown during autumn to obtain an early crop. Little is gained by this as a rule, and sowing in well-manured ground in February, when the soil is frost free, with successional sowings during March and April, is generally better in most gardens. The soil is broken down, finely raked, and the seed sown 9 in. apart in drills 3 in. deep, with 18 in. between each row. If double rows are sown 10 in. should be left between the rows, and 2 ft. between each pair of rows. Staking may be necessary. Plants from sowings under glass or under cloches in January may be used to obtain an earlier crop; the cloches should be removed in March and a further crop sown, and recloched.

Black aphis was a serious pest, but is now easily checked by pinching out the young tips and applying malathion or lindane as soon as any are seen. The pods may be used before the beans are fully developed and sliced as are runner beans, but normally they are picked when the beans are well formed but not tough.

Varieties: 'Aquadulce' and 'Green Masterpiece.'

Dwarf Beans (which include French, Kidney, and Haricot Beans) may be either used as young pods in a similar manner to runner beans or ripened in the pod for winter use. A rich well-manured soil gives the best results, and seeds sown during the first week in May, 2 in. deep and 6 in. apart, in drills 18 in. apart, may be followed by a second sowing at the end of May. The young plants should be thinned out to 1 ft. apart and small twigs used to stake them. If sown earlier, frost damage may occur. Seeds may also be sown in the greenhouse and the seedlings transplanted, or sown under cloches in the last week in March, provided the soil has been prewarmed.

The plants, as long as the pods are picked over frequently, will continue to bear until the frosts; a little liquid manure will be beneficial during the summer. A late sowing in July, cloched in September, will continue the season into the autumn.

If required for winter use (Haricot varieties) certain plants should be left unpicked and the pods allowed to ripen on the plants. They should not be picked green; if unripe when frosts come, the plants should be pulled up and dried in a shed.

Varieties: 'The Prince' (Cloche), 'Masterpiece,' and 'Comtesse de Chambord' (Haricot).

Runner Beans are the most popular type, and can be grown in two ways: either without stakes, in which case the tips of main and side shoots are regularly pinched out to make a bushy, dwarf plant, a method often used by farmers, or staked, with cross poles, allowing the plants to climb to the tops of the poles before pinching. Seed is sown from early May (mid-April under cloches) until late June, depending on the danger of frost, usually in a double row with drills 15 in. apart, and with seeds 3 in. deep and 6 in. apart in the rows, alternate plants being removed later.

Staking should be done as soon as the first pair of leaves unfolds, and a surface mulch is then applied. If the beans are to be dwarfed the rows should be about 18 in. or 2 ft. apart, and pinching may be required about once a week. A good, well-manured soil is essential, and plenty of moisture is required. The flowers may fail to set in dry weather, and an evening spray of water is helpful in preventing this "running off." Harvesting should be carried out regularly while the pods are young, before the seeds swell; older pods are stringy and seldom worth eating.

Varieties: 'White Czar' (white-flowered, heavy cropper) and 'Streamline.'

Beetroot.—From mid-April onwards varieties of beet may be sown on soil that has not recently been manured but is in good heart; on freshly manured soils coarse, forked roots subject to cracking occur. If in poor condition a light dressing of a complete fertiliser should be given before sowing. Sow in drill. 1 in. deep and 12 in. apart and make a first thinning to 4 in. apart when the first rough leaf appears, and a second later, leaving 9 in. between the plants. Transplanting is inadvisable. Early roots for summer pulling may be obtained from a sowing of a Globe type in mid-April, and the main sowing should be made during May or early June for the winter supply. A sowing under cloches in late February will provide roots for pulling in late May.

On a heavy soil the oval-rooted types are best, but on a lighter soil the long-rooted types may be used. A sowing in late July of the Globe type will provide beet for use at the end of winter. Salad beet from early sowings may be pulled as required; the main crop should be allowed to mature and is lifted in October before the roots become woody and tough. Any damaged roots should not be stored. Twist off the tops just above the roots, shake the soil from the roots, and store in boxes of sand or peat in a frost-free shed. If clamped outside, straw and a thick layer of soil should be used; if frost reaches them they are spoilt.

Varieties: globe—'Detroit Red,' 'Red Globe, and 'Crimson Globe'; oval—'Cobham Early'; long—'Cheltenham Green Top.'

Sugar beet is similar but is white, not red-fleshed, and is mainly a farm crop; if desired it may be grown in a similar manner. Care should be taken in hoeing all beet crops to avoid damage to the small surface roots which feed the swollen rootstock.

Borecole.—*See* Kale.

Brassica.—A generic name of vegetables usually known to gardeners as "greens." This group

includes brussels sprouts, cabbages, cauliflowers, kale, turnips, kohl-rabi, broccoli, and couve tronchuda. As they are all related, similar soil and cultural treatment is needed, and many pests and diseases are common to them. Each is dealt with under a separate heading.

Broccoli.—*See* Cauliflower.

Brussels Sprouts.—Young plants from seed sown thinly in a nursery seed bed during mid-March can be transplanted during May or June. The soil should be firm, well drained, in good heart, and contain adequate lime, some manure preferably having been dug in during the winter; a supplementary dressing of 2 oz. superphosphate and 1 oz. of sulphate of potash per square yard is given before planting. The young plants should be set out 3 ft. apart both ways, planted firmly, and watered in thoroughly. Regular hoeing is necessary, and about a month after planting a little soil should be drawn round the stems.

If growth seems weak a top dressing of nitro-chalk should be given and this repeated in early September. As the lower leaves yellow, cut them off and gather the sprouts as they mature, picking from the bottom of the stem. Where space is available a succession of sowings from March to June can be made to lengthen the cropping period.

Club root, the worst disease of brassicas, is kept in check by only using well-limed, well-drained soil, and dipping the roots in 4% calomel before planting, and cabbage root fly, a frequent insect pest, by using lindane.

Varieties: early—'Cambridge No. 1'; mid-season—'Rous Lench' and 'Triumph' (dark foliage, distinct).

Cabbage.—Sowings in March and April for summer use, in May or June for winter use, and in late July or August for spring use will give a succession of cabbages all the year round. Seed is sown thinly in a nursery bed of well-firmed, limed soil, clear of weeds, in drills ¾ in. deep and 6 in. apart, and the seedlings dusted with lindane to check flea beetle attack (prevalent with all brassica seedlings). All cabbages are gross feeders, and a well-drained soil in good heart, with adequate lime, is required.

"Spring cabbage" should be sown during late July (north) and August (south). If sown too early the plants may "bolt" without making a heart. The young plants are set out in mid-September 18 in. apart and with 18 in. between the rows if for hearting, or 9 in. apart with 18 in. between the rows, in which case the alternate plants are cut for "spring greens." On a heavy soil ridging along the rows of plants keeps the soil round the roots drained and helps to prevent loosening by frosts. In cold districts cloches may be used with advantage to help plants through the winter. In early March a dressing of 1 oz. per sq. yd. of sulphate of ammonia or nitro-chalk is a good stimulant.

Seed of "summer" and "autumn cabbage" is sown in March and April and planted during late May and June, 18 in. to 2 ft. each way between the plants, depending on the variety. The plants should be thoroughly watered, both before and after transplanting. A top dressing of 1 oz. per sq. yd. nitro-chalk may be given if required.

"Winter cabbage," maturing from October to February from sowings during May and early June, are set out 2 ft. apart each way in July or early August, usually on ground which has been cropped with early potatoes or peas. No nitrogen fertiliser should be given late in the season, as soft growth, liable to frost damage, is encouraged. A balanced fertiliser, such as "National Growmore," may be used if needed. When the stalks of cabbage are left standing over winter a common practice is to cut across the tops to obtain bunches of leaves, for use as greens during early spring.

"Savoy cabbages" mature during winter and early spring from seed sown in May. Seedlings are transplanted in late July and early August on to land manured for the previous crop, to which a dressing of 2 oz. superphosphate and 1 oz. sulphate of potash per sq. yd. has been applied. The young plants should be set out 2 ft. apart each way; they are exceptionally hardy, and should be grown in every garden in case of a hard winter.

Varieties: Spring sowing—autumn cutting, 'Greyhound' (early), 'Winningstradt,' autumn sowing—spring cutting, 'April,' 'Wheeler's Imperial.' Savoy 'Ormskirk Late' Green.'

Red cabbage is slow to mature; plants from sowings in August are transplanted 6 in. each way in autumn and set out in early spring 18 in. each way. They are ready to cut in late summer.

Cardoon (Cynara cardunculus).—Closely related to the globe artichoke and grown for the blanched hearts. Seed is sown in trenches 18 in. wide and 1 ft. deep; 3 in. of manure is worked into the bottom soil and covered with 3 in. of fine soil. Three or four seeds are dibbled in every 18 in. and covered with a flower pot till visible, and then thinned out, leaving one strong seedling at each station. Protection from sun and late frosts is provided by twigs over the trench, and copious watering is given during the summer.

On a fine day in September the plants are blanched by tying the leaves together and covering with dry hay, 3 in. thick, kept in position by raffia, and earthed up in the same way as celery. Blanching is completed in about a month.

Carrots.—A light, well-drained soil, enriched with decayed organic matter, is suitable for carrots. No fresh manure should be given, but a light dressing of "National Growmore" fertiliser can be applied prior to sowing. The surface is left rough until sowing time and then broken down to a fine tilth. The first sowing is made in early April in drills ¾ in. deep and 12 in. apart, and a succession is obtained by sowing at intervals of a month until the end of July.

On heavy, unfavourable soils stump-rooted varieties are best grown, long-rooted varieties needing a light soil. Thin out the stump-rooted varieties to 4 in. apart and the longer varieties to 6 in. Thinnings should be removed and the soil pressed firmly back to minimise damage by carrot fly. The early sowings are pulled as required, but the later sowings for winter use should be lifted in October and stored in slightly damp sand in a frost-proof shed or clamped in the open.

Frames and cloches are sometimes used to obtain early and late carrots. Seed of a quick-growing variety, such as 'Amsterdam Forcing' or 'Early Nantes,' sown in late January under cloches or in frames will provide an early crop; the same varieties sown in frames or cloches in early August will provide young carrots for the autumn. Carrot fly is a bad pest, especially on light soils; the seedlings should be dusted in the rows with lindane when 2–4 in. high to prevent the flies from egg laying.

Varieties: globular—'Early Gem'; stump-rooted—'French Short Horn'; intermediate—'Amsterdam Forcing' and 'Early Nantes'; long—'St. Valery' and 'Long Red Surrey.'

Catch Crops.—A term used for quick-growing crops interplanted between rows of other crops. Radishes between rows of broad beans, and lettuce between celery rows provide examples. In this way the best use of a limited amount of land can be made.

Cauliflower.—Broccoli is for all practical purposes a hardy winter cauliflower. Seed is sown ¾ in. deep in a nursery bed from mid-April to mid-May, depending on the variety, and transplanted during June and July on to firm soil, well manured for the previous crop. The plants are set out 2 ft. apart each way; 2 oz. superphosphate and ½ oz. of sulphate of potash per square yard may be hoed in before transplanting. No nitrogenous manure should be given late in the year.

Varieties: cauliflower—'Snowball' (summer), 'Majestic' (autumn). Broccoli—'Snow's Winter White' (winter), 'St. George' (early spring). Sprouting broccoli—'Nine Star Perennial' (a many-headed sort).

Sprouting broccoli is very hardy, has a more leafy head, and is cultivated in the same way. Purple- and green-sprouting sorts are grown also.

Summer cauliflowers require a soil which has been limed and manured during the winter; 1–2

oz. per sq. yd. of superphosphate should be given before transplanting. An early sowing in frames in February or March will provide plants for cropping in June. These should be hardened off and planted in March or April from 18 to 24 in. square, depending on the variety. Seed sown outdoors in April in drills ¾ in. deep will give plants for transplanting in May or June, for cropping from late July onwards. If growth is slow a dressing of 1 oz. per sq. yd. of sulphate of ammonia should be given. Leaves broken over the curds will help to prevent any damage from early frosts. Varieties given in previous paragraph.

Celeriac.—A plant allied to celery grown for its edible root, which resembles a turnip but has the flavour of celery; the stems are bitter to the taste and are not eaten. It is used in salads or boiled as other root crops.

Seed is sown in gentle heat in March and seedlings pricked out into seed-boxes, 2 in. apart each way. In June, after hardening off, the seedlings are planted out in shallow drills 18 in. apart, leaving 12 in. between each plant in the row. Water freely during the summer and remove side shoots as they appear. Lift the roots in October or November and store in a frost-free shed.

Celery.—Richly prepared ground is required. A trench 15 in. wide and 1 ft. deep is taken out and manure worked into the bottom of the trench. The soil is then returned to within 3 in. of the ground level. Seed should be sown in early March at about 60° Fahrenheit and the seedlings pricked out in deep boxes 3 in. each way and gradually hardened off. Celery seed is very fine, and care should be taken to cover it with only a fine layer of soil; if covered too deeply it may not germinate.

In late May or June set the plants out in staggered double rows 1 ft. apart, with 10 in. between the plants, and water them in. Frequent watering during the summer is required, and a light dressing of nitrate of soda will stimulate them if growth is poor. Before earthing up to blanch the plants, tie the stems loosely below the leaves and remove any suckers. Earthing up begins when the plants are about 15 in. high; the ground should be moist, and the first earthing should only be slight. The second and third earthings, at intervals of about three weeks, should be more generous, but should never reach higher than the base of the leaves, and no earth should fall into the heart. For exhibition purposes brown-paper collars may be tied round the stalks before earthing. The final earthing should cover all the stems right up to the leaves, and the soil should slope away neatly. In winter litter or bracken spread over the plants will help protect them from frost.

Celery fly is a serious pest, and the brown leaf-blisters should be pinched to kill the maggot inside and lindane applied two or three times at fortnightly intervals. Slugs are a serious pest and must be eradicated. This can be done easily with slug pellets or a liquid formulation of "Slugit." Leaf spot, a seed-borne disease, can be prevented by spraying with May & Baker's, "Bordeaux Mixture."

Varieties: white—'Solid White'; pink—'Clayworth Prize Pink'; red—'Standard Bearer' self-blanching—'Golden Self-Blanching.'

Chicory.—The young, blanched growths are used in winter salads. Seeds are sown in drills 1 ft. apart in May; the young seedlings are thinned to 8 in. apart and grown on until October or November, when they are lifted and the roots trimmed to 8 or 10 in. long. They are then planted in deep boxes in a moist, sandy soil 5 in. apart each way, leaving 1 in. above the soil surface, and the boxes put in a warm greenhouse or cellar.

No light must reach the crowns; one method sometimes used is to cover the crowns with 6 in. of sand. When the blanched growths show through they are about 6 in. high and ready for cutting.

Chives.—These are like small onions, and the leaves are used for flavouring salads and soups. They are easily grown in window boxes and town gardens. Bulbs can be planted in March 6 in. apart and divided when the clusters become too large.

Corn Salad or Lamb's Lettuce.—Occasionally grown for the leaves, which are used in early spring salads. Seed sown from August to October will provide plants for winter and spring use.

Couve Tronchuda.—A large brassica known as "Portugal cabbage," not generally suitable for smaller gardens. Seed is sown in March and the plants set out 2–3 ft. apart each way. The hearts may be cooked in the same way as cabbage.

Cress.—An annual growing rapidly from seed and used as a salad when only the seed leaves have developed. Seed sown as required, in boxes of light, moist soil and covered with brown paper until germination, when it is removed, will provide salad all the year round. The seed is merely pressed into the soil and the boxes kept moist. Cress may even be grown on damp flannel in a window.

Cucumber.—The cucumber of the shops is grown as a specialist crop under glass. Temperatures of 85° Fahrenheit or more may be required, and only occasionally are they grown by the amateur, although cloche and frame culture is now popular.

Ridge cucumbers, which are smaller and prickly outside, may be grown outdoors in summer. Plants from seed sown singly in pots under glass can be planted during late May on ridges of good, well-manured soil or, alternatively, sown on the ridges 1 in. deep at the same date. Water freely during the summer and cut the cucumbers while young to encourage further production.

If cloches are available greenhouse-raised cucumbers can be planted under them, in mid-April. Frame cucumbers are less hardy, but young plants raised under glass can be planted under cloches in early May.

Varieties: ridge—'King of the Ridge' and 'Stockwood Ridge'; frame—'Conqueror' and 'Telegraph.'

Endive.—Used in winter or autumn salads. Seed is sown during April in drills 18 in. apart and the seedlings thinned to 12–15 in. apart. Sowings in June and August will provide a succession. A rich soil and plenty of moisture are the main requirements; before eating blanching is necessary, as the leaves are very bitter. This is achieved by tying the leaves loosely together and covering the plants with inverted flower pots (with the holes blocked) to exclude the light; frost should be kept out by piling litter over the pots in winter. If cloches are used they can be coated inside with lime-wash to achieve the same effect. Alternatively, plants may be lifted in October and blanched in darkened frames.

Varieties: summer—'Green Curled'; winter—'Batavian Broad Leaved.'

Fennel.—A perennial culinary herb used in fish sauces and salads. Blanched stems may also be cooked in the same way as celery. Seed is sown in drills 2 ft. apart in rich soil and the seedlings thinned to 18 in.

French Beans.—*See* Dwarf Beans.

Garlic.—One or two "cloves" planted in February, 9 in. apart, will provide ample garlic for salads, as only a little is required. After growth is complete in summer the bulbs can be lifted, dried, and stored and some saved for replanting.

Haricot Beans.—*See* Dwarf Beans.

Herbs.—Many herbs are useful in small quantities for flavouring and garnishing, as well as being decorative. If possible, a separate herb garden should be made as a feature in the garden, or they

may be used as edging plants. Perennial herbs, of which borage, caraway, chamomile, chives, fennel, garlic, horseradish, lavender, mint, pennyroyal, marjoram, rosemary, rue, sage, tansy, tarragon, and thymes are the main types grown, should be given a permanent position. Those grown as annuals—anise, basil, coriander, dill, parsley, purslane, and summer savory—can be used as "fill-ins" on the vegetable garden. Brick and cobble paths associate well with herbs, imparting something of the character of the gardens of bygone days, when herb gardens were considered one of the most important features.

Horseradish.—A deep-rooting perennial herb which appreciates a well-manured, moist soil. It is easily propagated from root cuttings and can become a nuisance, as pieces of root left in the soil will make a new plant; care should be taken to lift the complete root when digging it for use. Straight roots planted in spring with the crowns 6 in. below soil level and 1 ft. apart can be lifted for use in autumn; no further treatment is required, apart from keeping weeds in check. Some of the roots should be kept for planting the following spring.

Kale.—Very useful during a cold winter, when other green vegetables are scarce, because of its hardiness. Seed sown in April or May will provide young plants for transplanting 18 in. apart each way in July or early August, on to a site used for peas or early potatoes, in good heart. A catch crop of lettuce can usually be taken from between the rows. The variety 'Hungry Gap' is usually sown in rows 18 in. apart where it is to mature and thinned, leaving 18 in. between the plants. There are many varieties; which types are grown is a matter of personal preference.
Varieties: 'Cottager's' and 'Hungry Gap.'

Kidney Beans.—*See* Dwarf Beans.

Kohl Rabi.—A brassica with a swollen stem base, in flavour and appearance something between a turnip and a cabbage. Seeds sown in April in rows 1 ft. apart are thinned to 1 ft. apart in the rows, and the swollen stem harvested when about the size of a tennis ball. If left to grow it becomes coarse.

Lamb's Lettuce.—*See* Corn Salad.

Leeks.—A vegetable which repays planting on a well-manured soil. If they are to follow winter greens, then manure or compost should be dug in after the previous crop is cleared. Leeks may be sown from early March to April in lines 8 in. apart on a prepared seed bed, and the seedlings transplanted as land becomes available during June and July, when about 6 in. high. Thinning in the seed bed should be unnecessary provided the sowing has been correct. The seedlings are set out 9 in. apart in rows 15 in. apart; a hole is made with a dibber, and each seedling dropped in and watered thoroughly. No firming is needed, the watering should tighten the plants sufficiently. Alternatively, drills 4 in. deep and 15 in. apart can be drawn out with a hoe and the plants put in 9 in. apart in the drills.
Regular hoeing is required, and a feed of sulphate of ammonia (1 oz. per gallon of water) can be applied if in poor growth. In September a little earth should be drawn up around the roots, which should, by then, be almost full grown. Leeks are very hardy and can be left in the soil until required for use.
Varieties: 'Lyon' and 'Musselburgh.'

Lettuce.—Two main types are grown: cos lettuce, a summer crop with long, straight leaves that curl inwards naturally or are tied in so that the heart is more or less blanched; and cabbage lettuce, which are broad and spreading, with round cabbage-like hearts, and are grown to supply salad all the year round. Lettuce should be grown on ground manured during autumn or winter, dug and left rough till planting time, when it is broken down and raked to a fine tilth.

This crop is a particularly valuable one for town gardens with restricted space. In these circumstances excellent returns can be had by raising seed indoors and pricking out the seedlings into small peat pots ("Root-o-Pots"). At this stage the plants can be grown on in a "Stewart" propogator which is simply a seed tray covered with a plastic hood, and finally planted out-of-doors in their pots. The practice can be repeated or small sowings made in the open and seedlings thinned to 9 in. apart. Quick, unchecked growth with plenty of moisture is essential; on poor soils peat can be forked into the surface and an application of liquid "Maxicrop" made during the growing season.
Varieties: wide selection available of all types; small, quick maturing sorts include 'Little Gem' ('Sugar Cos') and 'Continuity.'

Maize.—*See* Sweet Corn.

Marrows.—Pumpkins, gourds, bush, and trailing marrows all require similar treatment; plenty of sun and water and a rich soil, such as an old hotbed or compost heap, which will provide a porous medium of humus. Seed can be sown singly in pots under glass in March, or outdoors on the site in May. For cloches a bush variety must be used, and greenhouse-raised plants are clochedin mid-April. Plant four or five seeds in groups about 6 in. apart and 1 in. deep and finally thin to two plants 15 in. apart. Protection from late frosts may be necessary. Water copiously and hoe regularly. Cut marrows when about 12 in. long to encourage further fruits. Some can be left until they are full size and cut before the frosts, for storing in a dry, frost-proof place.
Varieties: bush—'Green Bush' and 'White Bush'; trailing—'Long Green Trailing.'

Melons.—Although usually a glasshouse crop, melons can be grown outdoors under cloches and in frames. Seed is sown under glass in April at 60° Fahrenheit, and seedlings can be set out 3 ft. apart in early May. The soil should be manured generously and the seedlings planted on a mound of compost mixed with soil. The plants must be stopped at the fourth or fifth leaf to encourage laterals. Two can be selected to grow on and, when 18 in. long, pinched out to obtain sub-laterals, which will bear the fruit. The female flowers may require pollinating, and on a sunny day a male flower or rabbit's tail can be used to transfer the pollen; as soon as the young fruits swell, remove all but two or three per plant and pinch back the laterals bearing fruit to two leaves from the melon. A feed of dried blood once a week, with plenty of watering (though not saturation!) will help the developing fruits. Light shading may be necessary.
Varieties: 'Dutch Net' and 'Tiger.'

Mint.—Easily grown from suckers in any soil. For winter use a few pieces can be planted in a frame. A number of varieties—'Apple Mint,' 'Peppermint,' and 'Spearmint'—can be grown besides common mint.

Mushrooms.—Growing mushrooms is really a specialist occupation. For the experimental amateur, beds of composted stable-manure are made up in a warm, damp cellar or disused air-raid shelter. Pieces of spawn are inserted when the temperature of the compost has dropped to about 70° Fahrenheit and the whole bed covered with an inch of inert sub-soil. The air temperature should be from 60° to 70° Fahrenheit, and in a few weeks mushrooms may appear. Full instructions will be given with the spawn, but it is advisable to consult a text-book dealing with the culture, as even for professional growers a crop is never certain.

Mustard.—Grown exactly in the same way as cress, but is ready two or three days earlier. If used together, mustard seed should be sown two or three days after cress. Again it is the seed leaves which are eaten.

Onions.—These respond well to good cultivation. The site is dug deeply in winter, manure

incorporated, and left rough until February, when it is broken down to a fine tilth and firmed well. Seed can be sown ¾ in. deep in drills during August and planted in March for exhibition onions, but the usual practice is to sow seed in late February outdoors or under glass in January and transplant during April in rows 12 in. apart with 6 in. between the onions, taking care to keep the bases about ½ in. below the surface. If sown outdoors and thinned the thinnings may be used in salads. Autumn-sown onions are liable to bolt, but less liable to attack by onion fly than spring-sown plants.

Dressings of a balanced feed can be applied but not after July, and in August the tops are bent over to hasten ripening. The chief pest is onion fly, the larvae of which eat the roots of the seedlings. Control can be maintained by sprinkling the seed drills with Murphy's "Gamma-BHC Dust" or applying a 4-in. band of the dust along the rows at the loop stage.

In small gardens, onion sets are popular. These are small onions grown in the previous summer, stored and replanted the next spring. Plant the bulbils 6 in. apart, leaving only the necks exposed.

Varieties: spring sowing—'Bedfordshire Champion,' 'Best of All,' and 'White Silverskin' (pickling); autumn sowing—'Giant Zittau,' 'Sutton's Solidity,' and 'White Lisbon' (salad onions); sets—'Ebenezer' and 'Stuttgarter Reisen.'

Parsley.—Sow thinly in rows 8 in. apart during March and again in July for a succession of young foliage; thin to 4 in. between plants.

Parsnip.—Grow parsnips on ground manured for a previous crop; if given fresh manure splitting and forked roots occur. Dig the soil deeply, and at sowing time in March, work the soil to a fine tilth. On a soil unsuitable for deep-rooted crops special holes 10–12 in. apart, filled with sifted soil, may be prepared. If this method has to be used four or five seeds are sown per hole; normally drills 15 in. apart and 1 in. deep are made and four or five seeds sown every 9 in. The seedlings are thinned, leaving one at each station. Parsnips should be left in the ground until needed; litter over the rows will ease lifting in frosty weather.

Varieties: 'Evesham' and 'Student.'

Peas.—Dig the ground well in autumn and add a generous amount of manure or compost. Seed sowing begins at the end of February, and can be continued at three-weekly intervals until early July. Under cloches sowings in January and October will lengthen the season. Both early and late sowings should be of a quick-maturing variety. Seed is sown in drills 6–8 in. wide and 3 in. deep, with 2 ft. between drills; the seeds can be scattered thinly in the drill or spaced 3 in. apart in a treble row. Cover with 2 or 3 in. of soil and as soon as the peas are about 2 in. high stake with twigs.

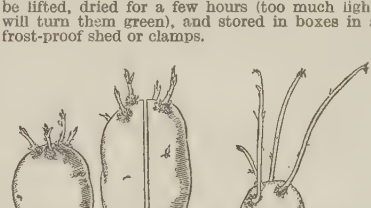
Failures are often due to attacks by birds and field-mice. The former should be discouraged by netting and the latter by trapping. Pea-sticks will be necessary for the taller varieties which should have 3–4 ft. between the rows. With limited space only the dwarf quick-maturing varieties should be used. A summer mulch will keep the soil moist, and picking should be done regularly.

Varieties: 1½–2 ft.—'Kelvedon Wonder,' 'Kelvedon Triumph,' and 'Meteor' (cloches); 2½ ft.—'Onward'; 3½–4 ft.—'Gladstone.'

Potatoes.—In general, it is only economic for the amateur to produce an early crop; the main winter supply can be grown if room and labour are available. They should be grown on land well manured the previous season, dressed at planting time with a mixed fertiliser, such as "National Growmore," at a rate of 1½ lb. to a 30-yd. row. The soil should not contain too much lime, as the damage of scab disease is increased.

"Seed" tubers about the size of a large egg are best used, and these can be bought or saved from the previous season's crop. Large potatoes may be cut leaving about three eyes to each part. New stocks should be bought occasionally if the "seed" is home saved to obviate risk of virus. "Seed" should be put in trays during February in a frost-proof shed to sprout, and in early April the "first-earlies" can be planted.

Drills 2 ft. apart and 4–5 in. deep are taken out and the sprouting "seed" planted 12 in. apart in the rows. Maincrop varieties are planted in early May 15 in. apart. The young growths should be protected from frost by earthing up slightly, and a further earthing is done as the potatoes mature. This practice of earthing prevents the tubers near the surface from becoming green when exposed to light, keeps weeds down, and protects the tubers from spores of potato blight, which are washed into the gullies. If growth is poor sulphate of ammonia can be applied at a rate of ½ lb. per 30-yd. row. Early varieties should mature in late July and later varieties in September and October; when the tops (haulm) turn yellow the crop can be lifted, dried for a few hours (too much light will turn them green), and stored in boxes in a frost-proof shed or clamps.



SEED POTATOES—Good seed is essential for first-rate crops. Illustration shows (*left*) a well-sprouted tuber, (*centre*) a large well-sprouted tuber suitable for cutting, and (*right*) a poor, badly sprouted tuber.

Potato blight is a common disease, and control by a spraying with maneb before the leaves touch in the rows is effective. Virus diseases, spread by greenfly, are checked by using "seed" from Scotland, where greenfly is less troublesome because of the lower temperatures. Colorado beetle should be watched for, and if found notified to the Ministry of Agriculture.

Varieties: Discerning growers will find the following well worth growing: 'Edzell Blue' (violet-coloured skin; excellent cooker), 'Pentland Dell' (white-fleshed; heavy cropper), 'Red Craigs Royal' (red-fleshed; heavy cropper), 'Ulster Chieftain' (white-fleshed, good early variety). Epicureans seeking a first-class potato should grow 'Maris Peer', a sort understandably gaining in popularity in Scotland, since its introduction. Another interesting sort is the Dutch-raised 'Record', a yellow-fleshed variety which has a trace of sweetness in its flavour.

Pumpkin.—*See* **Melon.**

Radish.—Although of the easiest culture, it is not grown as much as it should be due probably to the damage done by maggots of the cabbage root fly. This pest can be controlled by dusting the seed drills with Murphy's "Gamma-BHC Dust." Successional sowing can be made in the spring and again in early autumn if desired; summer-sown radish bolt, and are hot and tough.

Varieties: 'French Breakfast' (cylindrical) and 'Scarlet Globe' (round).

Rhubarb.—Before planting the ground should be generously manured and deeply dug. Crowns are planted in March, 3–4 ft. apart each way and mulched, but no rhubarb should be pulled until the following year, when a light pull can be taken. Remove any flowering shoots and give a dressing of sulphate of ammonia if growth is weak. Manure well each winter; if early supplies are needed, some of the crowns can be covered with inverted boxes or barrels and a packing of loose straw or bracken. An established, well-cultivated bed will continue almost indefinitely.

Sage.—A hardy shrub for the herb garden easily raised from cuttings. The leaves are harvested and dried in summer.

Salsify (Oyster Plant).—A winter root rather like a parsnip which requires similar growing conditions.

Savoy.—*See* Cabbage.

Scorzonera.—A winter root cultivated in the same way as salsify. It has a purplish root instead of the yellow-green one of salsify.

Sea-kale.—A perennial plant native to our seashores, which can be either grown from seed sown in March and left for two years to produce forcing crowns or from bought thongs, which are planted during March, 9 in. apart in groups of three, leaving 3 ft. between groups. During summer a manure mulch and nitrogenous fertiliser can be applied. When the tops die down in autumn the crowns are covered with boxes to force and blanch the new growths. Crowns can be covered in succession to keep a supply. Earlier sea-kale can be obtained by lifting crowns in November. These are planted in batches five or six to a pot, watered well, and a second pot, with the hole blocked, placed over them. In a warm greenhouse or similar position they should develop sufficiently for cutting in about three weeks. Slugs are the chief pest outside, and should be kept in check by a proprietary slug-killer.

Shallots.—A popular crop for the small garden. Shallots are purchased as bulbs, like small onions. A deep, well-manured soil is required, as for onions, and they are planted during February, the bulbs being pressed about half their length into soft soil, 6 in. apart in the rows, leaving 1 ft. between rows. In mid-July the little bunches of bulbs can be lifted. Leave them on the surface to dry for a few days and then store in a dry, frostproof shed. Some, about the size of a shilling, should be kept for planting the following year.

Spinach.—Sowings in February to April on a well-manured soil will provide a succession during the summer. Sow in drills 1 in. deep and 12 in. apart and thin the young plants to 3 in., and then to 6 in., using the second thinning to eat.

When green vegetables are expensive, in winter, the perpetual or prickly spinach is particularly valuable. Sow in August and treat as for the summer variety.

If plants are crowded or suffer from dryness, mildew can be troublesome. Therefore thin seedlings early and water whenever necessary. On poor soils, moisture can be conserved by mulching the rows with peat. Should growth be slow feed with liquid "Maxicrop" and repeat, if required.

Varieties: 'America' and 'Giant Prickly.'

Sprouting Broccoli.—*See* Cauliflower.

Sugar Beet.—*See* Beetroot.

Swede.—*See* Turnip.

Sweet Corn (Maize).—Gardeners should distinguish between the types of maize used for poultry food and those which supply sweet corn for human consumption. It is wise to use cloches for growing sweet corn, as it is only half-hardy and resents transplanting. Seeds sown under cloches in mid-April in two drills 12 in. apart and 1½ in. deep should be placed 1 ft. apart in staggered positions in the rows. More robust varieties may need 15 in. from plant to plant. A soil well manured for the previous crop is best used, and a mulch can be given as soon as the plants are a few inches high. The first cobs should be ready by mid-July, and should be eaten when the cob is milky.

Variety recommended: 'John Innes Hybrid.'

Tomato.—A sunny, sheltered site is required, otherwise ripening outdoors in our climate is uncertain. Sow seeds under glass in late March and harden off the plants in a cold frame or buy plants for setting out in late May or early June. The soil should be thoroughly dug and some artificial manure applied before planting. Allow 18 in. between plants and 2½ ft. between rows, and put in a strong stake with each plant. Keep to a single stem, pinching out side shoots regularly. When four or five trusses are set pinch out the top of the main shoot.

Feed with a liquid manure during summer. Fruit which fails to ripen outdoors can be gathered and stored at about 50° Fahrenheit or the plants laid flat on the ground and covered with cloches, when the tomatoes should ripen. Under cloches plants can be planted out in mid-April instead of late May, gaining six weeks growing time, and the Cloches removed when they become too large.

Potato blight attacks tomatoes, and a spray of maneb during the first week in August and repeated after fourteen days will give a control.

Varieties: 'Market King' and 'Moneymaker'; some heavy-cropping sorts have little or no flavour and a thick skin.

Turnips.—Ground manured the previous season should be dug well and dressed with 2 oz. superphosphate per square yard. A good early variety can be sown during April in drills ½ in. deep and 15 in. apart, followed by successional sowings at three-week intervals as required. The main crop for storage is sown in July and August, and seedlings should be thinned gradually to 10 in. apart. Use when about the size of tennis balls. A sowing can be made in September, left almost unthinned and the tops used as "greens" in spring. In autumn the storage crop is lifted and all undamaged roots put in sand in a shed or clamped. Flea beetle and turnip fly can be checked by lindane at the seedling stage.

Swedes are grown in a similar manner.

Varieties: turnips—'Early Milan' (summer) and 'Green Top Stone' (winter storage); swedes—'Purple Top.'

FERTILISERS AND ORGANIC MANURES.

The elements essential for healthy plant growth may be roughly grouped into classes—first, those required in some quantity, the major elements, nitrogen, potassium, and phosphorus; secondly, calcium, magnesium, and sulphur, which are required in lesser quantities; and thirdly, the trace elements, boron, manganese, iron, zinc, copper, and molybdenum, of which only minute quantities are needed. As well as the elements mentioned, others, such as silicon, aluminium, chlorine, nickel, and sodium, are often found on plant analysis, but the evidence that these are essential is inconclusive, though they may be beneficial to certain crops.

It is important to remember, when adding fertilisers to the soil, that different crops may require relatively more of one element than another, but a balance between all the elements is essential. As an instance, brassicas (the cabbage family) are gross nitrogen feeders, while root crops (*e.g.*, carrots) require far less nitrogen, and an excess may be harmful. A further point to notice is that although an element may be present in the soil the plant may be unable to absorb any because it is being kept in an insoluble state by excess of another element. An instance of this is the frequent yellow and sickly appearance of plants on very chalky soils due to lack of iron, which is present, but locked in an insoluble state by too much calcium.

The elements needed by the plant are in the form of various compounds, such as nitrates and phosphates, and may be applied as artificial fertilisers, which are manufactured, or as humus, which contains most of the foods required and

also provides the essential soil micro-organisms or bacteria, without which the soil would be inert and no plants would grow. Bacteria break down the complicated animal and vegetable matter of which humus is composed to soluble compounds which plants can absorb. Humus can be supplied as farmyard and poultry manure, leaf mould, compost, sewage sludge, spent hops, and from animal by-products like hoof and horn, dried blood, meat and bone meal, and many others.

Nitrogen is mainly concerned with vegetative growth, encouraging leaf and stem formation. It is also contained in chlorophyll, the green colouring matter of the plant, and one of the symptoms of nitrogen starvation is a pale-green colour to the leaf, indicating a lack of chlorophyll. Most of the nitrogen compounds used are soluble, and it is a wise maxim to apply "little and often"; if given in large doses much is washed through the soil and wasted.

Nitrogenous fertiliser should not be given to any plant late in the season, as sappy growth, easily damaged by winter cold and frosts, is encouraged. Similarly, at no time should large quantities be given to any plant, as this results in an excess of leafy growth, which is very susceptible to disease and adverse conditions of drought and cold; also plants tend to be later flowering.

Sulphate of ammonia is the most used inorganic nitrogenous fertiliser, and is excellent for spring use on seed beds, lawns, and early crops, and it is contained in most fertiliser mixtures. It makes soils acid in reaction, and if both lime and nitrogen are required, nitro-chalk should be used instead. Other nitrogen fertilisers used are potassium nitrate, which has the advantage of supplying two major elements at once, and is very soluble, and nitrate of soda, often used on beet and mangolds. The latter chemical should not be applied in excess, as too much sodium has a bad effect on soil structure. These inorganic fertilisers are all soluble and quick acting.

As a general guide, 1 oz. of the fertiliser to a gallon of water, applied at 1 oz. per sq. yd., is a good summer dressing, given at intervals of two or three weeks. It should always be given after rain or watering, and should be applied to the soil and not to the foliage.

Among organic fertilisers containing a percentage of easily available nitrogen are dried blood, soot, and meat and fish meals. Slower to decompose, and so having a more lasting effect, are shoddy (wool waste) and hoof and horn.

Phosphorus is concerned in the plant with the production of young cells of the root and shoot, and also encourages flower and fruit production and early ripening. Most of the compounds are relatively insoluble (rendering absorption by the plant difficult), and so large amounts can be supplied without deleterious effects, especially on acid soils, where the availability is less than on alkaline soils.

Phosphorus is generally applied to the soil in the form of phosphates, and among these superphosphate of lime is quick acting, and is usually applied at 2–3 oz. per sq. yd. in spring and summer, when the need is greatest. More slow acting is basic slag, a by-product of the steel industry, sold as a fine black powder and containing, besides phosphates, many of the trace elements, as well as a considerable percentage of lime. This is good for application to acid, wet soils, but should not be applied to potatoes owing to the risk of scab disease with the increase in the content of lime. It should not be applied with sulphate of ammonia. Bonemeal is also slow acting and also contains some nitrogen. It is excellent for crops like tomatoes, and is also used extensively for ornamental and pot plants.

Potassium, the third major element, is essential for good flower colour and ripeness in fruits. Dessert apples, potatoes, cereals, and root crops all need potash in some quantity, and if excess nitrogen has been applied a dressing of potash may counterbalance the effect. Sulphate of potash is the main inorganic compound in use. Muriate of potash (potassium chloride), to which some crops are sensitive, is much less used; it should be applied as a winter dressing before the crop is sown to lose the impurities by weathering. Sulphate of potash is purer, and may be applied during the growing season at 1 oz. per sq. yd. on the vegetable plot, and is used in many proprietary fertiliser mixtures.

Wood ash contains variable quantities of potassium, and provided that the ash has not been washed by rain and the potassium leached out, is a useful addition to the soil; bracken, cut during June and July, when large amounts of potassium are present in the foliage, can be composted when green to provide a good supply of the element.

Elements Required in Lesser Quantity.—Calcium, although required in small quantities in the plant, has profound effects on the soil. Its main function in the plant is in the production of the cell walls, but in the soil it helps to bind light soils together and to make the structure of sticky clay soils finer and more workable. Also soils without calcium are acid and tend to lock up some elements in an insoluble form. Addition of calcium changes the acidity, making it slightly alkaline or neutral, and releases the locked elements.

Calcium is applied as some form or derivative of calcium carbonate, commonly known as lime, which can be obtained in various forms. Hydrated or slaked lime (calcium hydroxide) is commonly used on clay soils, and chalk or ground limestone on lighter soils. Calcium is gradually leached from the soil, and it is necessary to replace it, or the soil becomes too acid and many crops will fail to grow. A normal dressing of lime for a vegetable garden is about 4 oz. lime or ½ lb. chalk per square yard every two or three years, and is best applied in autumn as a surface dressing after digging. It should not be applied together with other fertilisers. The amount of lime will depend on the type of soil, but it must be remembered that most vegetables grow best on a slightly acid soil.

Gypsum, or calcium sulphate, is sometimes recommended to supply calcium, but its solubility is negligible, and it is preferable to chalk or limestone only on soils containing salt due to sea flooding. It was used to help reclaim districts of East Anglia flooded by sea-water during the storm surge of January 1953 by improving the soil structure. Sulphur, as sulphates, and magnesium, as an impurity in limestone, are usually present in sufficient quantities for the plants' needs.

Trace Elements.—In the case of the trace elements most soils contain enough for the plant, but in certain circumstances deficiencies occur. Iron on very alkaline soils is insoluble and, as it is essential for the production of chlorophyll, deficiency results in the chlorosis of the leaves. It can be rectified by spraying the leaves with "Sequestrene"; likewise the lack of magnesium and manganese can be remedied where deficient on acidic soils.

Chlorosis in brassicas can be due to a deficiency of both manganese and magnesium. Boron deficiency, often occurring on light, calcareous soils, is responsible for brown heart of cauliflower and several other "diseases," mainly affecting the growing point. It can be rectified by applying borax to the soil at about 1 oz. per 15 sq. yd. Zinc and copper deficiencies are unusual in England, but lack of molybdenum has caused whiptail disease of cauliflower. Only minute quantities of the last three are required; more may be poisonous to plants and animals.

Organic Manures.—It should be noted that most of the deficiencies will not concern the amateur, especially if he keeps the ground in good heart with ample organic manure, which contains all the plant foods necessary. Well-rotted farmyard manure from cows and pigs is by far the best organic food, but is scarce now, good farmers returning it to their own land, and generally the material offered is low in nutrients. Poultry manure, which is rich in soluble nitrogen salts, is excellent either applied direct to the soil (not to the growing crop for fear of damage) or composted with straw.

There are many good substitutes for animal manure for use in generous quantities, *e.g.*, fallen leaves, seaweeds, spent hops from breweries and sawdust. With pine needles the latter is a useful inclusion in the compost heap and as a surface mulch helps to conserve soil moisture and suppress weeds. (Sawdust should not be used fresh but partially rotted.) With all these materials decomposition is speeded up by sprinkling with a nitrogenous fertiliser (*e.g.*, fish meal) at 2 oz. per sq. yd. The rough organic matter gradually breaks down to form humus, an essential ingredient for building up a rich soil structure which artificial fertilisers alone do not provide.

Among proprietary organic manures now available the seaweed-based "Maxicrop" has given good results on vegetables, flowers and lawns. Some others which mainly supply the necessary nitrogen to the soil are in the form of prepared sewage sludge which has been milled and dried. These may be bought locally at around 50p for 56 lb. Scottish gardeners are fortunate in having available a prepared by-product of the poultry industry known by the misleading name of "S.O.I.L.". In 1971 it was sold as cheap as 60p for 56 lb. and, like the others mentioned, can be used for a wide range of crops.

Compost Making.—The fertility of all soils is increased by the addition of humus. Texture too is improved, for on heavy clay drainage is sharpened and the soil lightened, while on poor sandy or chalky soils the water-holding capacity is increased.

Apart from buying humus-forming materials, like animal manure or peat, the compost heap is the most readily available source of plant food. The methods developed for making compost are numerous but all depend on three basic principles: (i) good aeration, (ii) plenty of moisture and (iii) a supply of nitrogen for the bacteria which bring about the decay of plant material.

A small compost heap can be had by making a loose-sided box about 4 ft. sq. with pieces of stout board 8 in. × 2 in., like that used by house-builders. As the heap grows in height, so the boards can be put in place until the box is 4–5 ft. high. Use all vegetable refuse like weeds, straw, lawn mowings and kitchen waste. Contrary to some opinion, autumn leaves of all sorts can be used. Hawthorn and oak, being rich in plant food, are particularly valuable, while horse chestnut and London plane which have a thick leaf stem take longer to decompose.

When the heap is about 9 in. high it should be sprinkled with a nitrogenous fertiliser like fish meal at 2 oz. per sq. yd., watered and, if possible, covered with a layer of soil. Then the process is repeated by building up another layer. The addition of soil will keep the heap moist and is a means of introducing a population of earthworms. To keep the compost sweet, a sprinkling of lime may be applied on top of each layer of soil. There are a few proprietary compost makers on the market which are said to "accelerate" decomposition but compost made in the way described is a well proven method.

In a properly made heap grass mowings and weeds previously treated with hormone weedkillers can be used. The bulk of compost may be increased by adding a layer of newspaper for each one of plant material. (The papers must be torn up first and not applied too thickly otherwise the rate of decomposition is slowed down.)

If time permits, a completed heap can be turned over after a month or two, re-covered with soil and thoroughly watered. Otherwise it can be left until rotted and used as required, putting any unrotted material as a base for a new heap. The time taken for rotting will vary with the time of year and the vegetable material used, but, as a guide, a heap made in the early summer can be used in the winter.

General Fertiliser.—Many firms supply compound fertilisers containing given amounts of the main nutrients needed, in either liquid or powder form, and some are made up with quantities of nitrogen, potassium, and phosphorus suitable for specific crops like roses, tomatoes, and chrysanthemums. A general fertiliser which can be made up by the amateur is as follows:

7 parts by weight superphosphate.
5 parts by weight sulphate of ammonia.
2 parts by weight sulphate of potash.

A mixture of this sort may be applied at 2–3 oz. per sq. yd. for feeding shrubberies, herbaceous borders or ground where annuals are to be grown.

Green Manuring.—Another method of enriching the soil with organic matter is green manuring, which has been practised for some time by farmers and can no doubt be adapted to the gardener's purpose. Green manuring consists of planting a fast-growing catch-crop and ploughing the mature crop back into the soil. Legumes are especially good for this, as certain bacteria in their roots can "fix" the nitrogen in the air. Field peas, sown at 4–5 oz. per sq. yd. and Italian rye grass at 2 oz. per sq. yd are commonly used, while clover and annual lupins are also suitable.

If sown after an early crop on land needing organic matter the green manure may be dug in during late summer. Alternatively, if the land is not being cropped at all during the year two green-manure crops may be grown; an early sowing of field peas in April may be dug in during July, and a further sowing of field peas or Italian rye grass sown immediately after may be dug in following the first few frosts.

New chemicals often appear on the market at exorbitant prices and with fantastic claims as to their value as "soil conditioners" and the like. Contrary to this generalisation, in recent years a chemical known as "Gibberellin" has been used to increase the growth of certain plants. It is now available to the amateur, but should be used with care and mainly in a spirit of experimentation, as no conclusive proof of its efficacy has yet been put forward.

GARDEN PESTS.

Every garden abounds in insects and other small creatures, but comparatively few species are pests which feed on plants. The great majority are quite harmless, while many are positively beneficial and help to keep the number of pests under control by catching and eating them. Every good gardener should make it his business to be able to differentiate between friend and foe. This is not always easy, but the speed of a creature's movements may often provide a clue. Fast-running, active creatures, such as the black ground-beetle or the centipede, are usually beneficial, while the slow-moving and sluggish ones, *e.g.*, wireworms, aphids and caterpillars, are usually pests. This is by no means an infallible rule, but it is handy to remember when in doubt.

The good gardener should also get to know the pests which are most prevalent in his district and which can be expected to crop up year after year. The first principle of good control measures is to act while an infestation is still in its early stages and before a great deal of damage is done. When one knows what to expect, steps can be taken to prevent an attack or to stop it developing to serious proportions.

Also, from the experience of past years one can often forecast whether a pest is likely to become numerous enough to make chemical treatment worthwhile. Remember, insecticides can become an expensive item, and there is little point in using them if the damage is negligible. In these circumstances insecticides may eventually increase the numbers of pests, since the treatment will also have killed off many of their natural enemies which had hitherto kept the pests under adequate control. In addition, good cultivation and general garden hygiene helps to reduce the numbers of pests.

The common pests of garden plants can be roughly divided into four main groups.

I. Root Pests.—These destroy the feeding mechanism of plants or tunnel into fleshy tap roots, tubers, and bulbs. Attacked plants make poor growth, and may eventually wilt and die.

Some insects are general root-feeders. These include (*a*) **Swift Moth Caterpillars**, soft, white caterpillars with reddish-brown heads; (*b*) **Chafer Grubs**, large, C-shaped, whitish grubs with chestnut-brown heads; (*c*) **Wireworms**, long, cylindrical, yellowish-brown grubs with a hard shiny skin; and (*d*) **Leatherjackets**, greyish-black grubs with a wrinkled, leathery skin. These are particularly prevalent in recently cultivated grassland or in gardens surrounded by fields, and will attack the roots of a wide range of plants. Chafer grubs, however, are particularly fond of the roots of shrubs, and wireworms will often tunnel in potato tubers and other fleshy roots, whereas leatherjackets prefer the roots of grasses, and may cause browning on large patches of lawn.

Badly infested ground should be dressed with lindane dust when cultivating, working the dust into the top 4 in. of soil. Where this is not possible, *i.e.*, on lawns or around established shrubs, the liquid form of the insecticide should be watered into the soil.

Cutworms are stout, fleshy caterpillars, varying in colour from greyish-brown to dingy green. They feed on roots during the day, but at night come to the surface and feed at the base of the stems of plants, causing them suddenly to collapse and wither. Brassicas and lettuce are commonly damaged in this way and the pests should be removed by hand and killed when the soil is cultivated.

Millepedes are hard-skinned, cylindrical creatures, brown or black, with numerous short, hair-like legs. They are slow-moving and curl up when disturbed. They should not be confused with the active, long-legged centipedes, which are beneficial. Millepedes commonly extend the damage made by other pests, such as slugs and wireworms. They also bore into the sown seeds of peas and beans. During the day they hide in dark, damp places, such as long vegetation or under stones and pieces of wood. Such hiding-places should be removed or dusted with lindane. Drills for pea and bean seed should also be dusted before covering.

Weevil Grubs, small, curved, white grubs, may infest the roots of pot plants and plants in rockeries. Such plants should be removed, the roots cleaned, and replanted in soil which has been dressed or mixed with lindane dust. Where it is not practicable to remove the plants they should be watered copiously with a liquid form of these insecticides and soil dressed properly at the earliest opportunity.

Slugs need no description. They vary greatly in colour. The most destructive are the underground keeled slugs, small, grey-black in colour, which tunnel in roots, tubers, and bulbs. There are also several foliage-feeding species which rasp holes in the top parts of plants. Slugs like wet conditions, and much can be done to control them by ensuring that the soil is well-drained and that long, tangled vegetation is removed.

Poison baits can be bought or made by mixing 1 oz. metaldehyde with 3 lb. bran (or bonemeal for keeled slugs). The bait is sprinkled over the infested ground or distributed in small heaps and protected from the rain. There is also available on the market a metaldehyde spray for dealing with the foliage-feeding types.

Cabbage Root Fly attacks brassicas and wallflowers. The small white maggot eats away the side roots and tunnels in the main root, causing the plant to wilt and collapse. The roots of young seedlings should be dipped in lindane before planting out. Alternatively, the plants can be given a drench of lindane within four days of planting out.

The maggots also tunnel in radishes and turnips, and this can be avoided by dusting the seed drills with lindane.

Carrot Fly.—The maggot of this fly tunnels in carrots and parsnips. Where the pest is serious it is best to delay sowing until the end of May. If possible, seeds should be sown in exposed, windy places, which are avoided by the egg-laying flies. Seedlings should be dusted or sprayed when 2–4 in. high with Murphy's "Lindex Garden Spray," an approved chemical.

Onion Fly maggots tunnel into the bulbs of onions, leeks, and shallots, causing the foliage to collapse. Dig out attacked plants carefully, ensuring that parts of them are not left in the soil, and burn them. To prevent attacks dust around the seedlings with lindane when they are at the "loop" stage, *i.e.*, about 1 in. high, and again ten days later.

Narcissus Bulb Flies are serious pests of narcissi and also snowdrops and other bulbous plants. The maggots burrow in the centre of the bulbs, causing them to rot. All soft bulbs should be burned and the remainder immersed for three hours in a solution of lindane containing a wetter. To prevent future attacks and a reinfestation, dust around the necks of growing bulbs with lindane at fortnightly intervals from the end of April until the end of June.

Insects which feed above ground include:

II. Sucking Pests pierce the tissues of plants with needle-like mouth parts and suck the sap. This devitalises the plant, checks growth, and causes wilting. Some species cause distortion of leaves and young shoots, and aphids, suckers, scale insects, and mealy bugs excrete a sugary fluid which disfigures the foliage, attracts ants, and allows the growth of sooty moulds.

Aphids, *i.e.*, blackfly, greenfly, etc., are serious pests which attack almost all plants and multiply rapidly in warm weather. They feed on the shoots and undersides of the leaves, and many species are responsible for the transmission of virus diseases. Infestations should be treated as early as possible. Malathion and nicotine both give excellent results if used properly and thoroughly to both the surface and undersides of the affected foliage. With the advent of these sprays the control of aphids on roses and broad beans, for example, is no longer a serious problem.

Tree fruits should be sprayed when the buds are bursting and again when the flower buds are still green. Currants should be treated at the "grape" stage, but lindane should not be used on this fruit. Tar oil, applied to deciduous woody plants while they are completely dormant, will kill the overwintering stages of these and many other pests. It does not, however, give a good winter control for Woolly Aphid on apples. This pest is best controlled by spraying at the pink-bud stage with B.H.C. with a succinate spreader added. Small colonies on the bark can be eradicated by painting with 10% tar oil.

Some aphids feed underground on roots, particularly of lettuces, currants, and cacti. Where practicable, infested plants should be lifted and the roots cleaned and sprayed before replanting in clean soil. Otherwise water them copiously with malathion or lindane.

Scale Insects are often found in greenhouses, but also occur out-of-doors on trees and shrubs. Flat or dome-shaped, these creatures spend most of their lives immobile, and they do not at all resemble insects, or even appear to be alive. Again tar oil is useful for killing the overwintering stages on deciduous woody shrubs which are dormant. Plants which are in leaf should be sprayed with malathion or nicotine/white oil emulsion two or three times at fortnightly intervals. These substances are more effective if as much as possible of the scale is first removed by means of a sponge, brush, or scraper with water in which soft soap has been dissolved. **Mealy Bugs** are common pests of greenhouse plants, and should be given the same treatment as scale insects.

Capsid Bugs are very active insects which cause considerable damage to fruit trees and bushes and also to various ornamental plants, principally

chrysanthemums and dahlias. They feed on the young leaves, causing distortion and raggedness, and on the buds, which later produce misshapen blooms. These insects, green or reddish in colour, can be controlled by spraying with lindane when the flower buds are still green as, for instance, on fruit trees. Herbaceous plants should be sprayed twice or three times at three-weekly intervals, starting when the plants are young and before the damage is seen. Less persistent insecticides which can be used in this case are malathion and nicotine.

Leafhoppers are small, yellowish-green insects like aphids but much more active. They feed on the undersides of the leaves of a variety of plants, causing them to become speckled with yellow. Roses are commonly attacked. The treatment given to capsids on herbaceous plants will control these also, the sprays being directed to the undersides of the leaves.

Whiteflies are serious pests in greenhouses, and also occur out-of-doors on rhododendrons and other evergreen shrubs. The adults are like miniature moths with white wings, and the young are small, scale-like creatures, generally greenish in colour, which feed without movement on the undersides of the leaves. To control all whiteflies lindane or malathion should be used as a spray or smoke, two to three applications being given at fortnightly intervals.

Red Spider Mites are extremely small creatures, red or greenish in colour and just visible with the naked eye. They feed on the undersides of the leaves of many greenhouse and outdoor plants, including fruit, causing the leaves to turn sickly yellow. Control is difficult, the most effective materials being malathion, derris, summer ovicides, or azobenzene smoke. The directions on the labels of these products should be followed carefully.

III. Biting Insects have chewing and biting mouth parts which are used to cut away pieces of plants.

Caterpillars (the young stages of moths and butterflies) are the best-known pests in this group. They vary in size and colour according to the species, and most plants are liable to be attacked. These should be sprayed or dusted with derris as soon as the damage is noticed.

On apple and pear trees caterpillars can cause serious trouble and, in this case, treatment should take the form of a pre-blossom spray with trichlorphon.

The greatest problem with caterpillars arises with the well-known large and small white butterflies which in some seasons skeletonise the leaves. The worst damage is in the late summer when the infestation has built up to its highest point. Control is laborious; crush the egg clusters of the large butterfly and remove colonies of caterpillars by hand. As far as chemical control is concerned, this should be restricted to the use of derris up to within two weeks of picking. In recent years various other chemical controls have been suggested and applied on a large scale but their use is not now recommended unless specific approval has been granted. *See* T31.

Sawfly Caterpillars are very similar to those above, and commonly attack gooseberry and rose foliage. They can be controlled by spraying with malathion or derris.

Attacks by the Apple Sawfly, which burrows in young apples and forms ribbon-like scars on the skin, can be prevented by spraying with lindane seven days after 80% of the blossom has fallen.

Beetles and Weevils which feed on foliage are usually best controlled by spraying or dusting with derris. To kill the tiny Flea-beetles which eat small holes in the seedlings of brassicas and turnips, treat the plants at fourteen-day intervals until they reach the " rough-leaf " stage.

The golden-brown Raspberry Beetle, which feeds on the flowers and whose grub tunnels in the fruit, is best eradicated with derris applied ten days after full bloom and again ten days later. For other common pests in this group, *e.g.*, Vine Weevil, Clay-coloured Weevil, Pea and Bean Weevil, etc., apply the derris as soon as the damage is first seen

Earwigs feed at night on the foliage and flower petals of many plants. They hide by day inside flowers, in the folds of leaves, and in nooks and crannies on the ground, under flat stones, etc. These pests are killed by derris applied to the plants (but not to open flowers) and to their hiding-places.

Leaf Miners are very small grubs which tunnel between the upper and lower surfaces of leaves, forming pale blisters, as on lilac, holly, celery, etc., or long, twisting galleries, as on chrysanthemum, pea, and tomato. In small infestations the affected leaves should be picked off and burned. Otherwise spray with lindane as soon as the damage starts, giving three applications at fourteen-day intervals.

IV. Eelworms are microscopic pests which are invisible to the naked eye. They are able to live for very long periods without food and are extremely difficult to eradicate. The most common species are:

Stem and Bulb Eelworm, which infests narcissus, phlox, strawberry, hyacinth, onion, and other plants. Infested plants show distorted foliage and dwarfing and gradually deteriorate. They can only be sterilised by immersion in hot water kept at well-defined temperatures for one to three hours, but expert diagnosis and advice should be obtained before this or any other control is attempted. Infested ground must be kept clear of any host plants for at least three years to starve out the eelworms.

Chrysanthemum Eelworm causes the formation of yellowish blotches between the veins of chrysanthemum leaves, which later turn black and drop off. In severe infestations the blooms are undersized and malformed. Expert advice should be obtained before control measures are attempted.

Potato Root Eelworm is a serious and widespread pest of potatoes, causing the plants to become stunted and sickly, giving very poor yields. The pest can only be kept in check by crop rotation, potatoes being grown on the same ground only once in four years. This is difficult in small gardens, and where land becomes heavily infested the only remedy is to rest it from potatoes for at least five years.

The Purchase and Use of Insecticides.—To ensure that an insecticide will do what the maker claims, it is advisable only to buy brands which have been tested and approved by the Ministry of Agriculture. This can be ascertained from the Approval Mark (T31) on the label. Read the directions and following them carefully. Never apply insecticides to flowers in bloom, otherwise many valuable pollinating insects will be killed.

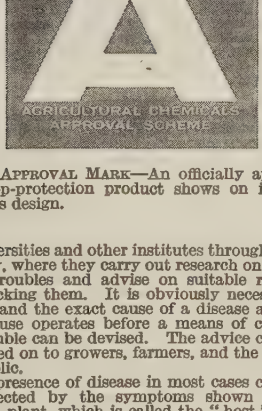
DISEASES OF PLANTS.

Plant diseases are important because they can cause great loss not only in growing crops but also in the produce after it has been harvested and stored. The skill in growing crops is wasted if they are destroyed by disease, and many people know the wastage of potatoes through blight disease in winter stores and rotting of onions when they decay through neck rot disease. For these reasons the keen gardener must take notice of

diseases and use the knowledge available to him in checking them wherever possible.

The most important point to remember about plant diseases is to recognise the first signs so that the remedy can be applied at once. In greenhouses this is of great importance because the atmosphere is warm and moist, and in such conditions diseases flourish. It must also be remembered that the same crop is often grown in the same soil in a greenhouse so that we get a build-up of disease, and this causes the well-known "soil sickness." This means that new soil must be brought in or the old soil enriched and also sterilised by steam or by chemicals. Even frames and propagating pits require periodic cleaning up by a disinfection treatment.

Unlike insect pests, the actual cause of a plant disease cannot be seen with the naked eye, and microscopic examination is required for its detection. The scientists who study diseases are called plant pathologists, and these are stationed



THE APPROVAL MARK—An officially approved crop-protection product shows on its label this design.

at universities and other institutes throughout the country, where they carry out research on various plant troubles and advise on suitable remedies for checking them. It is obviously necessary to understand the exact cause of a disease and how that cause operates before a means of checking the trouble can be devised. The advice can then be passed on to growers, farmers, and the gardening public.

The presence of disease in most cases can only be detected by the symptoms shown by the affected plant, which is called the "host" plant. The actual cause must then be determined by careful examination in the laboratory, which is done by the pathologist.

Plant diseases in general are divided into three classes as follows: 1. Fungus and Bacterial. 2. Virus. 3. Functional Disorders.

1. Fungus and Bacterial Diseases.—The first kind called fungus diseases are caused by the attack of fungus parasites; examples being the well-known club root of cabbages, potato scab, apple scab, and plum brown rot. These parasitic fungi are microscopic and composed of fine threads, but they attack plants and penetrate them either through wounds (insect bites, hail damage, pruning cuts) or directly through the surface cells (epidermis). The threads grow into the plant, killing the cells and absorbing their contents. There is usually some discoloration or even decay of the tissues around the point of infection, but it is possible for the plant to show distress in one part although the parasite is at work some distance away. Examples are silver leaf in plums and the honey fungus, which kills trees by attacking the roots.

The fungus spreads by means of spores which are equivalent to seeds in flowering plants but which are microscopic in size. These spores are produced on the surface of the plant in enormous numbers and are blown (wind), splashed (rain), or carried (insects, etc.) in all directions to alight on other healthy plants, where they germinate and spread the disease. This occurs in the growing season, but when winter approaches, the parasite forms tough, resting bodies of one kind or another, and these are resistant to extreme cold.

They overwinter in the soil or in the surface of tree bark, etc., so that in the following spring they can germinate and cause disease again. So we get the reappearance of such troubles as damping off in seedlings, scab in apples, brown rot in apples and plums, foot rot in peas, wart disease in potatoes, mildews on all kinds of plants, and so on. This question of soil contamination by overwintering spores is one of the most serious in the fight against plant disease.

The signs of fungus and bacterial diseases are varied, and may show as yellowing, silvering, brown spotting, or blackening of leaves (potato blight, rose black spot, celery leaf spot, antirrhinum rust), as stunting (cabbage wire stem), as pustules and cankers in stems (coral spot, apple canker), as gumming or dieback in branches (rose canker, plum dieback), as galls, warts, witches brooms, or other malformation (club root in cabbages, crown gall, leafy gall, peach leaf curl), as dry or soft rots of fruits, tubers, vegetable bulbs, and corms (gladiolus dry rot, potato dry rot, iris rhizome rot, celery heart rot), and many other abnormal conditions. Sometimes only a part of the plant is affected and can be removed, *e.g.*, branches showing attack by coral spot or one of the large bracket fungi seen on trees, these having gained entrance through a wound.

2. Virus Diseases.—This class of disease is becoming increasingly important as more is discovered about them, although research on them is a comparatively recent development. A virus disease is caused by infection with a virus, and the exact nature of this is not yet clearly understood, but it is so small that it cannot be seen with ordinary microscopes. Its detection is therefore not easy, but when the sap of a virus-diseased plant is injected into a healthy one it causes the disease.

In nature this spread is brought about by biting and sucking insects, which are referred to as Vectors. They transmit the virus by feeding on infected plants and then travelling to healthy ones, on which they feed and so spread the disease. Most viruses are transmitted by aphids (greenflies).

In the garden and nursery they can be carried from plant to plant by pruning knives or by the fingers in the process of trimming plants such as tomatoes, melons, and cucumbers or by the use of the knife in taking cuttings. In general, the virus does not kill a plant quickly but tends to cripple it and cause a slow deterioration. Infected plants cannot recover but remain, sometimes for years, as sources of infection on which insects feed and carry on the disease. So viruses may increase in lily stocks, strawberry beds, and raspberry plantations unless virus-infected plants are removed and aphids strictly suppressed.

The signs of virus disease are of different kinds, but the commonest are those of the type called mosaic, in which the leaves show a mottling with light-green or yellow patches scattered in irregular fashion on the darker green of the leaf. There may be also some reduction in the leaf blades. These symptoms can be seen in the mosaic of cucumber, vegetable marrow, lettuce, cabbage, turnip, tomato, delphinium, primula, dahlia, apple, raspberry, and many other common plants. In some, such as lilies, daffodils, and onions, the mosaic is more in the form of stripes down the leaf blades.

Another virus symptom is flower "breaking," where the normal colour of the petals is broken by streaks and spots of white, and this can be seen in tulip, wallflower, pansy, stocks, or carnations affected by the mosaic virus. Other viruses cause bronzing of the top leaves (as in tomato spotted wilt) or small light-coloured rings arranged in concentric circles (as in dahlia ring spot) or even reduction of leaves until they are tendril like (as in tomato fern leaf). Sometimes there is malformation or even proliferation, producing innumerable stunted shoots, as in blackberry dwarf disease.

The important point to note about these virus diseases is that every part of the plant is quickly

infected, so that the sap is infectious to other plants of the same kind. The virus is present in all parts, and for this reason it is useless to propagate from a virus-infected plant. This means that all the scales and offsets from bulbs such as lilies and tulips, all the tubers from potatoes, and all cuttings from herbaceous plants which are taken from a virus-infected plant are useless, because they will carry the virus. They should be destroyed, and the only exception is where the plant is greatly valued, in which case seed can be taken from it before it is destroyed. In general, viruses do not travel in the seed, and only in one or two cases is seed infected, and this only in negligible quantity.

3. Functional Disorders.—This third class of disease is often called non-parasitic, because unlike the previous two kinds there is no parasite involved, and these troubles are therefore not infectious. They are due to faulty cultivation or unsuitable environment, in which soil conditions or climate affect the plants adversely. In this group we include cases of unsatisfactory growth due to waterlogging, drought, frost, high temperature, damage by fumes or atmospheric pollution, or even excess lime.

Perhaps the most important kinds of trouble in this class are the so called **Deficiency Diseases,** where the plants suffer from shortage of some important food. This may be one of the common food substances, such as nitrogen, potash, or phosphate, and details will be found under the section on manures and fertilisers (T26).

CONTROL OF DISEASES.

1 Garden Hygiene.—The control of plant diseases can be dealt with only briefly, but to begin with we must emphasise the value of good cultivation as an insurance against losses from disease. Robust plants are better able to stand up to disease than sickly ones, and everything in the way of proper drainage, soil aeration, proper spacing, sensible feeding, and so on, will help to keep the plants vigorous, and this is the first line of defence against diseases. Garden hygiene is important, weeds need to be kept down, wounds in trees and shrubs covered with a good paint against infection, new stocks examined carefully, seed bought only from reliable sources, diseased plants burnt, and dead material regularly removed from plants, especially in greenhouses.

2. **Soil Sterilisation.**—There are other precautions, among which the sterilisation of the soil in greenhouses by means of steam or chemicals is of some importance. Dazomet can be used outside but rotation of crops is a most useful system in helping to avoid disease. Disinfection of frames, propagating pits, and seed boxes by formalin or cresylic acid are other useful measures.

All these operations aim at destroying the resting spores of fungus parasites responsible for such diseases as tomato leaf mould, gladiolus dry rot, damping off in seedlings, root rots, and downy mildews of many kinds in young plants such as stocks, cheiranthus, cineraria, tomato, aster, and calceolaria when grown in boxes or pots.

3. Disease Resistant Plants.—The use of disease-resistant varieties of plants is very desirable, but there are not many kinds available, and often the resistant kind does not possess flowers or fruit of such fine quality or flavour as the more susceptible kind. The outstanding success of this kind is that of potatoes immune to the dreaded wart disease, and these can be grown safely in the most heavily infected land. There are antirrhinums resistant to rust disease, and there is resistance in some degree in the case of delphinium mildew, potato blight, tomato leaf mould, and some others. Research goes on to discover still more, because any such plants are always worth a trial.

4. Treatment of Seeds and Bulbs.—For seed-borne diseases seed treatments may be done with captan or thiram seed dressings, or even by immersion of the infected seed in warm water.

In some diseases, for example, tulip fire, we can protect the bulbs from the danger of infected soil by raking in a powder such as "Botrilex" when planting the bulbs, and a similar treatment is done with calomel dust against club root in beds intended for sowing brassica seeds.

5. Fungicides.—Even after all this, a disease may still appear in the crop, and more direct action must be taken. It is then necessary to protect the plants by means of a **Fungicide.** This is a chemical which is poisonous to fungus parasites but which will not harm the crop plant (host). Fungicides are used as wet sprays or in powder form as dusts, and they are sprayed or dusted all over the plants to protect them from infection by diseases.

The object of the treatment is to cover the plants with a film of the fungicide so as to protect the still healthy ones. To help the spray fluid to spread over and adhere to the foliage another substance, called a wetter, spreader, or sticker, is added to the spray, but sometimes this is already included by the manufacturer.

5. (*a*) Sprays.—Sprays are applied by means of machines called sprayers which vary from small, hand-syringe types giving a continuous jet of spray to those pumped up to a pressure and carried on the back (knapsack machines), and so on to the large machines driven by a petrol engine, which deliver the spray at a high pressure. It is necessary to have a suitable nozzle giving a fine mist-like cone of spray which settles on the foliage and is not wasted.

5. (*b*) Dusts.—Dusts are similar chemicals produced in such finely divided form that the powder can be blown over and on the foliage almost like a fog. This is best done after a shower of rain or after a heavy dew. The machines used are far more varied in design than spraying machines. There are small hand dusters worked either like a small pump or like a bellows, of which the "Acme" is a good example, and there are those which are carried on the back and worked as a double-bellows action or on the front of the body with a rotary-fan action. It is important in gardens to clean and dry the machines after use, and small sprayers may be best put upside down to drain for a time after use.

The substances used as sprays and dusts against plant diseases for many years have been copper and sulphur and their compounds. Perhaps the best known copper-containing spray is "Bordeaux Mixture," which is still a good spray, but which has been largely replaced by liquid copper available as "Murphy's Liquid Copper Fungicide" for such diseases as tomato blight, etc. Sulphur is used extensively as lime-sulphur against apple scab and as colloidal sulphur against the powdery mildew diseases. As dusts, copper is mixed with lime to give copper–lime dust and sulphur is used alone either as flowers of sulphur or green sulphur.

5. (*c*) The Newer Fungicides.—In recent years much research has been carried out in tests to see whether other chemicals have value as fungicides, and the search has been in the field of organic chemistry and among all kinds of these chemicals. Tests of this kind take a long time, but a few substances have already been picked out as showing special promise and we can mention captan which is so good against apple and pear scab, zineb against tomato leaf mould, onion mildew and tulip fire and dinocap against any of the powdery mildews such as American gooseberry mildew, strawberry mildew, vine mildew as well as the same diseases on ornamental roses, delphiniums, michaelmas daisies and other plants.

6. Control of Viruses.—The control of virus diseases is very different, because in this case the only spray treatments likely to be of use are those designed to keep down insects. The other necessary control measure is to remove and destroy the virus-infected plants, which are a danger as sources of infection.

This is best done when the plants are young, so that any young marrows, cucumbers, dahlias, delphiniums, sweet peas, lupins, lilies, etc., which show virus symptoms as commonly revealed in leaf mottling and poor growth should be removed as soon as detected. Propagation should be done carefully, so that young stock is not propagated from stocks of strawberries, raspberries, and all kinds of herbaceous perennials which show signs of virus infection. Even the knife used for taking cuttings should be wiped occasionally on a rag dipped in a good disinfectant.

7. Prevention of Functional Disorders.—In the case of Functional Disorders (non-parasitic diseases) it is not always easy to advise remedies. Where the soil conditions are faulty attention can be directed to improving drainage if necessary or counteracting dryness by digging in humus, irrigating, and general mulching. Dryness at the roots of tomatoes causes loss of fruit, and so does extreme dryness in the air of the greenhouse, but these should be adjusted fairly easily.

Hail damage can spoil many crops, but robust foliage may help a little to lessen the damage. Late frost damage to fruit in some areas can be lessened by various methods of cultivation and planting. The effects of drought can be aggravated by shortage of certain foods, especially potash, so that even here some attempt can be made to avoid loss. Excess liming may cause food shortages by causing the appearance, in the leaves, of a yellowish or even whitish colour, which is known as lime-induced chlorosis. The real reason may be lack of iron or manganese due to the excess lime in the soil, but recently very good results at counteracting this condition have been obtained by using the substance known as "Sequestrene."

Another method of treating these food shortages is to spray the young foliage in early summer with the required element in a very weak solution. They can even be included in sprays used for keeping down diseases or pests. It must not be forgotten that even the ordinary foods, such as nitrogen, potash, and phosphate, may sometimes be in short supply, and the effect can be seen by the trained plant pathologist. In these cases the effect may not always show clearly in the growing crop, but may appear long afterwards in the stored fruits and vegetables, which as a result deteriorate and break down long before they are required for use.

The present-day methods of cultivating large numbers of the same plant in one spot tend to increase the risk of large-scale disease attacks. Modern plants may be highly bred and selected for great purity of strain. Indeed, they have often been chosen for fine quality and flavour, with little regard to their ability to resist disease, so that the gardener must always be ready to give them the protection they may need.

USES OF MODERN WEEDKILLERS.

The eradication of weeds by chemical means is one of the greatest advances of recent years albeit the value of herbicides is still unappreciated by most gardeners. With a planned programme, all cultivated ground and lawns can be kept free of weeds without hoeing or any other sort of manual cultivation.

Occasionally troubles have arisen in not following makers' instructions. Sometimes the damage has been most unfortunate, as the majority of herbicides are toxic, in varying degrees, to a wide range of plant life. In the main, controls are determined by circumstance, as typified in the following cases:

Asparagus Beds.—Annuals and top growth of perennial weeds can be controlled with cresylic acid in the autumn and before the asparagus appears in the spring. In beds free of perennials, a first-class control of weeds can be maintained with Simazine applied in the early spring.

Where annual and perennial grasses predominate, Dalapon or Diquat will give good control. As for bindweed, this may be eradicated by watering the foliage with 2,4-D in late July or August taking care to avoid contact with the asparagus stems and particularly the fern.

Fruit Garden.—Around fruit trees and bushes, grasses and perennial weeds can be controlled with diquat. This only kills the foliage but repeated applications during the growing season will clear the ground. Once free of perennials, annual weeds may be controlled effectively by an application of simazine each spring.

Garden Paths.—The introduction of new herbicides has made the control of weeds in garden paths an easy matter. For the purpose, mixtures of different herbicides are available in small packs under the names of "Kilweed" and "Super Weedex." As both contain simazine they remain active in the soil for a long period killing off germinating seedlings. For this reason, once paths have been cleared of weeds an annual application is all that is required to prevent a reinfestation.

Success is dependent on careful use as the herbicides must be distributed evenly, at the correct dosage in the spring and early summer. They are used in solution and application is made by a can with a fine rose or, better still, with a sprinkler bar attachment.

Lawns.—The majority of weeds in turf can be eradicated easily with formulations of 2,4-D or M.C.P.A. (*see* Finding List). In particular, daisies, dandelions, plantains, and most broad-leaved weeds are susceptible although it may be necessary to repeat the dose after 10 days. The best time to do the work is on a warm, fine day in the spring when the plants are growing actively and there is the prospect of fine weather to follow for twenty-four hours.

The action of the herbicides is rapid, and grass may be cut after a couple of days, composting with mowings in the normal way. It appears that the hormones are not injurious to bacterial life in the soil and in a few weeks break down into harmless substances.

Where bulbs are naturalised in grass, steps to control weeds should not be taken until the foliage of the bulbs has died down and the bulbs are dormant. Thus, as a general rule, control measures are best applied throughout July.

To deal with weeds in turf where there arises the danger of the spray—or even a drift from it—touching cultivated plants nearby, as, for instance on grass paths in a rose garden, then one of the plastic canes filled with a solution of hormone can be used to spot-treat weeds.

Some weeds are resistant to normal doses of hormones and need special treatment. These are mostly mat-forming plants of low-growing habit which are not cut off by mowing. Typical examples include mosses of all sorts, speedwell or veronica, yarrow, and yellow-flowered clover. Here, the main control must be in the use of lawn sand, a good mixture of which can be made up with:

2 parts by weight sulphate of ammonia.
1 part by weight sulphate of iron.
13 parts by weight LIME-FREE sand.

Where moss is the most prevalent weed, to the mixture should be added sufficient superphosphate to give 1 oz. of it per sq. yd. for the area to be treated. Alternatively, patches of moss can be dusted with a formulation of mercurous chloride like "Mos-Tox." This will kill the weed but generous feeding should be given to prevent reinfestation.

Applications of lawn sand to weeds should be made when the turf is damp and there is the prospect of fine weather; if a period of drought follows an application, then water should be applied to avoid serious scorching. Repeat the treatment as necessary throughout the growing season.

Linked with this "spot" treatment, the growth of grass must be encouraged, as this will tend to smother low-growing weeds. Thus, in the early spring when the turf is wet, feed with a mixture

of equal parts or superphosphate, sulphate of ammonia and dry soil at 2 oz. per sq. yd. over the whole area and repeat after a month, if desirable. In addition, do *not* shave off the grass by close cutting instead, the blades of the mower should be set reasonably high for a whole season.

Where fertility is low, clovers often predominate in turf. The Dutch clovers with white—or pink—flowers and a white-angled band towards the base of each leaflet, can be eradicated with Mecoprop. Afterwards the turf should be fed with nitrogenous fertilisers like soot and sulphate of ammonia, to discourage reinfestation. Other types of clover found in turf are species of *Trifolium*. Compared to the Dutch clover, these have a tight, bunched habit of growth and yellow flowers. All of them are resistant to hormones and, in addition to manurial treatment, should be treated with lawn sand.

Lakes.—It sometimes happens that aquatic plants with large floating leaves, such as water lilies, get out of hand. Here, control can be established by cutting off the foliage with a long-handled appliance like the "Corypu Water Scythe." The work should be done early in June and repeated as often as any fresh growth is seen.

Bulrushes are difficult to eliminate, but can be destroyed by digging out the roots when the level of the water permits. Dalapon has been found to give a control; applications should be made, with a wetting agent added, when the rushes reach maturity.

Ponds.—Problems of weed control in ornamental ponds are often not easy to solve. Where duckweed is prevalent this small floating plant can be eliminated by sweeping the surface of the water at regular intervals. If this practice is carried out thoroughly much of the vegetative growth will be eliminated, and the plant will not be able to form resting bodies whereby it overwinters. Once a control has been established, further spread of the plant can be prevented by introducing a few moorhens or ornamental ducks.

The most common of unwanted plants in pools is blanket weed. There is no single means of dealing with this plant, for its spread is governed, to a certain extent, by unbalanced plant and animal life in the water. With this fact in mind, water lilies should be established so that their foliage shades about 25 per cent of the water. In addition, a few oxygenating plants should be introduced from local ponds or streams and a supply of goldfish added. Blanket weed is usually found in pools where the water gets overheated in summer; for this reason, the average depth of garden ponds should be a minimum of 2 ft. and preferably a minimum of 3 ft.

Rose Beds.—A complete control of annual weeds among roses can be obtained with Simazine. Here, the salient point is to apply the herbicide immediately after pruning in March *before* any weed growth starts. Alternatively, Diquat can be used in April or early May and the application repeated as necessary.

Shrubberies.—With a shortage of labour, beds of shrubs are often weed infested. Perennials can be eradicated with Diquat and annuals controlled by this treatment as they appear. Alternatively, once the perennials are removed, the ground can be kept clear with Simazine used in the early spring.

Much to check weeds in shrubberies can be done by mulching the surface of the soil with heavy dressings of peat, fallen leaves, or sawdust; if the weeds push through the mulch, a second application should be made at once.

Vacant Ground.—On land free of crops all plants can be killed by watering the herbage with sodium chlorate at 1 lb. to a gallon of water. In some cases repetition may be necessary. When using this method it should be remembered that treated ground will remain toxic to plant life for a period of up to six months; if doubt exists about the persistence of the chlorate in the soil, then it is advisable to wait for the appearance of annual weeds before planting.

Apart from its persistence, sodium chlorate is prone to seep through soil and affect plants for some distance away. To avoid danger of fire from clothes being soaked in a solution of the chlorate and then dried, it is prudent to use a formulation with an additive to reduce the risk of fire. (*See* **Finding List.**) Where couch grass is predominant then the best control is to be obtained with Dalapon.

SPECIAL PROBLEMS OF WEED CONTROL.

Bindweed.—Probably the most ubiquitous of all garden weeds. Up to the present time the main control has been to carefully fork out the roots as new growth is seen; if this is done methodically the plant can be eliminated within a reasonable time.

Lately, chemicals have come to the fore, and bindweed may now be eliminated by watering or painting the foliage with a formulation of 2,4-D when the annual growth has nearly reached maturity. Thus, first applications can be applied in July and the treatment repeated, if necessary, to good effect. Where the weed is among cultivated plants, the herbicides must be applied with a paint brush or the foliage rubbed with a cloth damped in a solution. When doing this rubber gloves should be worn.

Blanket Weed.—*See* **Ponds.**

Bracken.—Horticulturally, control is not a big problem, and in limited areas it is easily dealt with by repeatedly cutting the aerial stems with a grass hook as the first fronds open. This practice will exhaust the underground food supply of the plant, and gradually it will die out. The young fronds are rich in plant food and, while still green and fresh, they should be composted. No chemicals will offer a reasonable control of this plant and, indeed, it is best dealt with by cutting and final digging out of the roots.

Couch Grass.—Where the soil is light and tends to be low in fertility, it is often found that this is a difficult plant to eradicate by cultural means. If the long, underground stems are forked out in the conventional manner and left on the surface to dry, the roots may be composted to advantage and a good control established. To prevent reinfestation, manures and fertilisers should be applied generously and the ground kept hoed regularly.

Chemically, couch grass can be killed easily by watering the foliage with Dalapon.

Ground Elder.—Without question this is one of the worst garden weeds and, whether or not the fact is pleasant or acceptable, it is indubitably a weed of neglected ground. In varying degrees it is resistant to hormone weed-killers of all sorts. On ground free of crops it may be reduced by an application of sodium chlorate, as explained in the paragraph **Vacant Ground.** The first treatment should be made as soon as growth starts in the spring and repeated if the desired effect is not abundantly clear. When ground elder is to be found among herbaceous plants the cultivated plants must be lifted out and the weed removed by repeated hand-forking.

In shrubberies reasonable control can be had by smothering the young growth in the spring with a thick dressing of peat, leaf mould, baled straw, or sawdust. If growth penetrates the surface dressing it will be found that the etiolated shoots are not difficult to remove by hand, or a second layer can be applied to complete the treatment.

Alternatively, the foliage of ground elder can be watered with Diquat and the treatment repeated once or twice during the growing season.

Horsetail.—This is sometimes erroneously called marestail and on poor, sandy soils it is often a common weed. Fortunately, recent experiments have proved that it can be easily controlled by spraying or painting the *mature* growths with a formulation of 2,4-D, taking care, of course, to keep the spray off cultivated plants near by. As the appearance of horsetail is symptomatic of low fertility, manurial treatment should be carried out on a generous scale. Where the weed is growing among cultivated crops, individual stems must be treated separately as recommended for bindweed.

Marestail.—*See* **Horsetail.**

Moss.—*See* Lawns (T33).

Nettles.—It is difficult to understand why the perennial nettle is so abundant as it is immediately responsive to applications of 2,4-D and 2,4,5-T made any time during the growing season. The annual nettle is usually proved a denizen of rich, light soils and may be eradicated with cresylic acid, Diquat or 2,4-D.

Oxalis.—Of all weeds this is probably the most difficult to destroy. It is easily identified by its large, trifoliolate leaves like that of clover. Unlike other weeds, oxalis cannot be efficiently removed by hand, as this disturbs the bulbils clustered around the base of the stem of mature plants. On ground free of crops, sodium chlorate can be applied in March (*see* Vacant Ground). Perhaps a second application may be necessary, but, even so, control may not be complete. Among shrubby plants, it may be possible to eradicate the weed by smothering, as suggested in the paragraph on ground elder.

The foliage can be killed with Diquat and, by repeated applications, this may constitute the best means of control.

Speedwell.—*See* Veronica.

Veronica.—This procumbent, blue-flowered weed of turf is sometimes know as speedwell. Being resistant to hormones, its control may only be established with lawn sand. *See also* Lawns.

Woody Plants.—With or without the addition of 2,4-D, these may be killed with 2,4,5-T. This hormone is particularly useful on bramble, gorse, ivy, and other unwanted shrubby plants. It is necessary to thoroughly saturate the foliage of deciduous trees, and the best results are obtainable when the leaves are fully mature but not starting to die off. In the case of ivy, the dormant shoots should be generously sprayed for the best results.

Yarrow.—A weed found in many lawns where its presence often signifies low fertility. Control is with lawn sand. *See* Lawns (T33).

Summary.—From these notes it will be seen that there are many aids for dealing with weeds. The salient point is to get the *right* method for *each* plant. Equally important is to check the reason why certain weeds grow profusely under some conditions. Very often this natural tendency can be counteracted as in the case of phosphatic fertilisers against moss and in the application of organic manures and chemical fertilizers where horsetail and yarrow are concerned.

HORTICULTURAL SOCIETIES.

There are many specialist societies in Britain. Detailed information on particular plants is normally available from them, and membership is open to all wishing to join. The most prominent societies are:

Alpine Garden Society
Sec. Michael Upward, 58 Denison House, 296 Vauxhall Bridge Road, S.W.1.

Auricula and Primula Society, The National
Sec. A. Marlow, 2 Glebe Close, Thornford, Sherborne, Dorset.

Begonia Society, The National Society of England and Wales
Sec. F. J. Martin, 50 Woodlands Farm Road, Erdington, Birmingham 24.

Cactus and Succulent Society of Great Britain
Sec. R. H. I. Read, 5 Wilbury Avenue, Cheam, Surrey.

Camellia Society, The International
Sec. Charles E. Puddle, V.M.H., Bodnant, Tal-y-Cafn, Denbighshire.

Carnation Society, The British National
Sec. E. Allman, 1 Woodham Rd., Catford, London, S.E.6.

Chrysanthemum Society, The National
Sec. S. G. Gosling, 65 St. Margaret's Avenue, Whetstone, N.20.

Daffodil Society
Sec. D. J. Pearce, College of Ascension, Selly Oak, Birmingham, 29.

Dahlia Society, The National
Sec. P. Damp, 26 Burns Road, Lillington, Leamington Spa, Warwickshire.

Delphinium Society, The
Sec. C. J. H. Topping, B.A., Ph.D., 5 Park Lane, Sevenoaks, Kent.

Floral Arrangement Societies of Great Britain, National Association of
Sec. Mrs. F. C. Dobson, 21A Denbigh Street, London, S.W.1.

Fuchsia Society, The British
Sec. C. H. Leytham, 72 Ash Lane, Hale, Altringham, Cheshire.

Gladiolus Society, The British
Sec. K. S. Wright, 223 Frinsbury Hill, Frinsbury, Rochester, Kent.

Hardy Plant Society
Sec. Miss B. White, 10 St. Barnabas Rd., Emmer Green, Reading, Berks.

Heather Society, The
Sec. Mrs. C. I. MacLeod, Yew Trees, Horley Row, Horley, Surrey.

Iris Society, The British
Sec. Mrs. T. A. Blanco White, 72 South Hill Park, London, N.W.3.

Northern Horticultural Society, The
Harlow Car Gardens, Harrogate.

Pansy and Viola Society, The North of England
Sec. F. C. Marshland, 2 Jubilee Mount, West Lillands, Brighouse, Yorks.

Pelargonium and Geranium Society, The British
Sec. H. J. Wood, 129 Aylesford Avenue, Bechenham, Kent.

Pteridological Society, The British
Sec. J. W. Dyce, 46 Sedley Rise, Loughton, Essex.

Rose Society, The Royal National
Sec. L. G. Turner, Chiswell Green Lane, St. Albans, Herts.

Royal Horticultural Society
Sec. John Hamer, M.B.E., B.A., Royal Horticultural Society's Offices, Vincent Square, S.W.1.

Royal Caledonian Horticultural Society
Sec. John Turnbull, D.S.O., D.F.C., C.A., Royal Caledonian Horticultural Society, 44 Melville Street, Edinburgh 3.

Saintpaulia and Houseplant Society
Sec. C. O. Pringle, St Martin Close, Church Road, Eastleigh, Hants.

Scottish Rock Garden Club
Sec. Mrs. L. C. Boyd-Harvey, Boonslie, Dirleton, East Lothian.

Sweet Pea Society, The National
Sec. R. J. Huntley, 431 Wokingham Road, Earley, Reading, Berks.

Vegetable Society, The National
Sec. W. C. Cooper, 288 Northumberland Avenue, Welling, Kent.

FINDING LIST FOR WEEDKILLERS

All the herbicides in this list are first-rate chemicals available in small packs suitable for use by amateur gardeners. Unless otherwise stated all the formulations have been approved by the Ministry of Agriculture. In case of difficulty in obtaining any of them, the manufacturers should be contacted.

The list may appear unnecessarily long but the pipe-dream of multipurpose herbicides is not a reality and the full extent and value of chemical weed controls are only obtained by using herbicides for their specific purposes; as such, they constitute an efficient and economic method of eradicating unwanted plants of all sorts.

Weedkillers for Use on Turf

Trade names	Chemicals	Manufacturers	Type of action	Plants controlled	Notes and precautions
"Bugges 2,4-D"	2,4-D	Bugges Insecticides Ltd. Sittingbourne, Kent.	Hormone growth regulator translocated throughout the plant.	Many broad-leafed weeds and some perennial ones. Best hormone type for killing daisies, dandelions and plantains. Particularly good for dealing with pearlwort.	Primarily for use on lawns. Beware of drift.
"Dicotox"		May and Baker Ltd., Dagenham, Essex.			
"Shell Weedkill"		Shell Chemical Co. Ltd., Shell Centre, London S.E.1.			
"Lornox"		Boots Pure Drug Co. Ltd., Nottingham.			
"Bugges MCPA"	MCPA	Bugges Insecticides Ltd.	Hormone growth regulator translocated throughout the plant.	Many broad-leafed weeds and some perennial ones. Best hormone type for killing creeping buttercup. Repeat application after 14 days if necessary.	Primarily for use on lawns. Beware of drift; on small areas the powdered formulation in puffer pack can be used.
"Weed-a-Lawn"		Pan Britannica Industries Ltd., Britannica House, Waltham Cross, Herts.			
"Clovotox"	Mecoprop	May and Baker Ltd.	Hormone growth regulator translocated throughout the plant.	Best control for white-flowered clover, chickweeds and field woodrush. Useful against pearlwort with repeated applications.	Primarily for use on lawns. Beware of drift.
"Lawn Clover Killer"		Pan Britannica Industries Ltd.			
"pbi Calomel Dust"	Mercurous Chloride	Pan Britannica Industries Ltd.	Scorching of foliage and inhibition of development.	Mosses and fungi.	The use of this chloride should be confined to mosses and fungi. It is of no manurial value.
"Boots Moss Killer"		Boots Pure Drug Co. Ltd.			
"Mos-Tox"		May & Baker Ltd.			
"ITP Mercurated Moss Killer"	Mercurous Chloride + Sulphate iron and Sulphate ammonia	International Toxin Products Ltd., Bramford, Nr. Ipswich, Suffolk.			
Lawn sand	*See* T33(2).	Usually home made.	Scorching of annual growth. Of herbicidal and manurial value.	Invaluable against weeds resistant or semi-resistant to hormones, like pearlwort, moss, veronica (speedwell), yellow-flowered clover and yarrow.	*See* Lawns (T33(2)) for detailed information.
"Velves Lawn Sand"		Pan Britannica Industries Ltd.			

Weedkillers for Garden Use

Trade names	Chemicals	Manufacturers	Type of action	Plants controlled	Notes and precautions
"Nova Soil Steriliser"	Cresylic Acid	The Murphy Chemical Co. Ltd., Wheathampsted, St. Albans, Herts.	Contact herbicide.	For destruction of growth of annual weeds and top growth of perennials.	Particularly valuable on asparagus beds and where annual weeds have to be controlled. Also used as a soil sterilant.
"Bugges Dalapon"	Dalapon	Bugges Insecticides Ltd.	Translocated throughout the plant, killing vegetation by movement from leaves to roots.	Annual grasses, couch grass, sedges, reeds and bulrushes.	Delay planting for 40 days after application. May be used, upon maker instructions, as a selective herbicide on asparagus, shrubberies, fruit gardens, etc.
"Weedol"	Diquat Salt	Plant Protection Ltd., Yalding, Kent.	Translocated throughout the plant but with scorching effect similar to contact herbicides.	Kills annual weeds and top growth of perennials. One of the few herbicides to give a good control of ground elder. Selective only by application, i.e. kills all foliage it contacts.	Undoubtedly one of the most valuable and interesting herbicides to be introduced. Inactivated upon contact with soil; no residual effects. Available in small packs. Can be stored from season to season.
"Path Weed Control"	Simazine	Boots Pure Drug Co. Ltd.	Soil acting, killing seedling vegetation by uptake through roots.	Controls germinating seeds of many weeds over a long period.	Apply when ground is wet in early spring on asparagus, apples, pears (not plums), soft fruit, ornamental trees and shrubs including roses. Slow acting.
"Weedex"		Fisons Horticultural Ltd., Harvest House, Felixstowe, Suffolk.			
"Boots Bramble, Brushwood and Nettle Killer"	2,4,5-T	Boots Pure Drug Co., Ltd.	Hormone growth regulator translocated throughout the plant.	Special value in control of woody plants like brambles, brushwood and ivy. Also good against nettles.	Beware of drift.
"Kilnet"	2,4,5-T + 2,4-D	May and Baker Ltd.			

Weedkillers for Use on Drives and Garden Paths: in addition to their use among cultivated plants, some herbicides can be used for weed control on garden paths.

"Kilweed"	Aminotriazole + MCPA and simazine	Fisons Horticultural Ltd.	Enters the plants through leaves and roots and is readily translocated.	All broad-leafed weeds found in paths. Gives lasting protection against seedling weeds.	In all cases of weed control on paths, apply carefully and thoroughly to ensure even distribution of the herbicide.
"Super Weedex"	Aminotriazole + simazine	Plant Protection Ltd.			
"Pathclear"	Diquat Salt + simazine	Plant Protection Ltd.	Enters the plants through leaves and roots and is readily translocated.	All weeds of garden paths and seedling weeds.	Not on the List of Approved Chemicals.
"Double Strength Weedkiller"	Phenals	Plant Protection Ltd.	Contact with foliage but is not persistent.	Kills plant foliage but chief use is in dealing with moss.	Not on the List of Approved Chemicals.
"Path weed control"	Simazine	Boots Pure Drug Co.	Soil acting, killing seedling vegetation by uptake through the roots.	Once established weeds are eradicated will keep paths free of reinfestation.	Slow acting; persistent in the soil.
"Weedex"		Fisons Horticultural Ltd.			

CARE OF INDOOR PLANTS

By definition a house plant is one which can be permanently grown for decoration indoors. Such plants should not be confused with orchids, crotons, hibiscus, and the like, for these are really greenhouse plants or denizens of Scandinavian or American houses, where heat and air conditions may be automatically controlled. Conversely, the average British home is often cold and draughty, and has a high temperature in the evening and a very low one at night. This is far from satisfactory, but, in view of the fact, the cultivator of house plants must choose subjects tolerant of existing conditions.

Cultural Conditions.—Ideally, the temperature should be kept as constant as possible, and in cold weather plants grown in window-boxes are best moved nightly into the centre of the room to avoid damage by frost. Linked with temperature is the question of humidity, for plants respond well to a moist atmosphere. Here again the majority of rooms are ill-suited for growing plants. The condition can be improved, however, by sinking the pots in peat or wrapping them around with sphagnum moss. Alternatively, pots may be stood on a layer of gravel which can be kept damp without allowing water to seep through the bottom of the pot and thereby saturating the soil.

Other factors influence the health of plants indoors—gas fumes, for example, and draughts—so both must be avoided if possible. It will also be found that dust collects on the foliage, therefore plants with large leaves should be sponged regularly with soapy water. Others, with hairy leaves, like saintpaulia, may be gently sprayed, but the water must not be allowed to remain on the foliage, as it may lead to scorching or rotting.

Of all cultural practices, the most important is watering. Unfortunately, the right way and time to do this cannot be laid down emphatically, but as a general guide, plants may become *nearly* dry before watering and then be given a *thorough* soak by standing the pots up to their rims in a bucket of water. For all plants, rain-water is best; if tap water has to be used, it should reach the same temperature as that of the room before being applied.

Soils and Potting.—However well a plant has been grown, the turning point culturally is in its repotting, as from this juncture it either grows vigorously or soon declines. The important factor is to get the correct compost. This may vary slightly, but an all-round mixture can be made up of:

7 parts by loose bulk medium loam
3 parts by loose bulk granulated peat (or leaf soil)
2 parts by loose bulk coarse, gritty sand

This mixture is the basis of John Innes Potting Compost and, with fertilisers added, can be purchased in small quantities from horticultural sundriesmen. If fertilisers are not added, plants should be fed during the growing season at about fortnightly intervals (depending on the particular plant) with a dilute solution of liquid animal manure; alternatively, 2 oz. of the following mixture dissolved in a gallon of rain-water can be used:

5 parts by weight of sulphate of ammonia
7 parts by weight of superphosphate
2 parts by weight of sulphate of potash

Normally a plant will grow satisfactorily in the same soil for three or four years. After this annual growth may be poor, together with yellowing or dropping of the foliage. The plant is then in immediate need of repotting. To do this a large crock should be put into the bottom of the new pot—which should be generally a shade larger—followed by a little compost. Then the matted roots of the plant can be teased out with a pointed stick, put in the pot and more compost worked firmly around the roots.

Some plants, of which palms are an example, prove intolerant of root damage, and repotting must be done with particular care, but, nevertheless, the compost must be made firm. When repotting is not absolutely necessary, the top inch of soil can be taken off annually and the pot top-dressed with fresh compost. Both repotting and top-dressing are best done before growth starts in the spring.

Propagation.—Many house plants are easy to propagate from cuttings or layered shoots. The former are taken off the parent plant at a joint in the stem by severing cleanly with a razor blade. After the lower leaves have been removed, the stems are inserted into a mixture of equal parts of sand and peat in a pot. A glass tumbler or specially-made, small, plastic tent is then placed over the top to avoid loss of moisture, and in a week or two rooting will have taken place.

As for layering, this can be done by bending a shoot into a pot of sandy soil and pegging it down at a joint. When the layer has rooted it can be severed from the parent.

Health of Plants.—Fortunately the number of pests and diseases affecting indoor plants is small, and the large majority of troubles are due to faulty cultivation. Occasionally aphids (green or black flies) may be found on young growth, and can be destroyed by carefully wiping affected leaves and shoots with water containing a little detergent, repeating the practice if necessary. On ivies, in particular, sometimes a brown, waxy scale can be found. Underneath the protective scale is a small insect which sucks the sap, and without difficulty these can be removed by hand.

Another insect occasionally seen is the mealy bug, an aphid which is surrounded by a prominent coating of a white, woolly substance; control in this case is to paint individuals with a dab of methylated spirits and to deal regularly with any reinfestation.

Basal rotting of flower stems and leaves, to be seen often on cyclamen and peperomias, is due to fungal infection, but this can be avoided by attention to correct watering and temperature. Similarly, premature yellowing of the foliage and leaf dropping is primarily a cultural trouble brought about by excessive cold, draughts, gas fumes, dryness, over-watering, perhaps over-feeding, or a combination of some of these factors.

SELECTION OF PLANTS FOR GROWING INDOORS

For ease of reference the following list includes plants which can be grown as permanent features indoors and florists' plants like cyclamen and primulas. These latter sorts are normally purchased in bloom and discarded when flowering finishes.

Araucaria excelsa (Norfolk Island Pine).—Because of its likeness to a small fir tree, it is a plant to stand on its own. It is not difficult to grow if kept out of the full sun and the soil moist. One of the earliest plants adopted for growing indoors, but not often seen at present.

Azalea.—Varieties in a wide range of colours are sold in late autumn and early winter. The plants are imported from Belgium and forced by English nurserymen. Azaleas need generous watering, preferably by immersion, in order to soak the root ball thoroughly. After flowering plants may be stood out of doors in the summer and kept moist but normally do not flower freely again for two or three years.

Begonia.—An enormous genus of plants of world-wide distribution, many being suitable for indoor cultivation. The large-flowered sorts known as tuberous begonias are potted in the early spring and kept in a temperature of 65–70°F. Once the growth starts, water freely and feed fortnightly. After flowering gradually withhold water and then store the corms until the following spring. Bud drop and yellowing of the leaves is usually due to faulty watering or draughts.

Billbergia nutans.—This is a member of the pineapple family, the Bromeliads, having typically narrow, spiny-edged leaves. Nearly hardy and will flower in a warm room. Do not re-pot unless absolutely necessary, as the roots are best confined.

Campanula isophylla (Harebell).— A charming blue-flowered plant with a long flowering period. Easily grown in cool conditions, and its pendulous habit it useful for a basket. After flowering, remove dead flower-heads and trim straggly shoots. There is a good white form, *alba*.

Cacti.—Innumerable sorts are used as house plants. In the main, all should be grown in a sandy, gritty soil with sharp drainage; water may be given freely in the summer, but withheld in winter, except to prevent the soil drying out. Two cacti which will flower freely and are particularly worthy of cultivation are *Aporocactus flagelliformis*, the rat's tail cactus, and *Epiphyllum ackermanii*. Both are tolerant of poor conditions and neglect.

Mention should also be made of the old-fashioned Christmas cactus, *Schlumbergera bridgesii*, as a great favourite, but an infinitely more exciting one of a similar type is the rare *Rhipsalidopsis gaertneri* with bright red flowers. These two are both easy to grow if the soil is kept on the moist side.

Chlorophytum elatum.—This plant will tolerate a range of temperature and responds to occasional feeding in the summer. It is most attractive, with its green leaves striped with cream-coloured bands. A good plant for beginners.

Christmas or White Cherry.—*See* Solanum capsicastrum.

Cineraria.—Normally plants are bought in flower in the winter. They require cool conditions, good light, but not full sun, and care in watering. Numerous varieties have been raised with their daisy-like flowers ranging in colour from white to red and violet-blue. In nature the cineraria is a perennial, but the hybrids are not worth keeping once flowering is over.

Crassula.—Shrubby members of this genus make fine house plants, growing well in light soil in full sun. Particularly valuable are *C. lactea*—which has white flowers annually and large, succulent, spoon-shaped foliage—and *C. falcata*, a choice plant with red and yellow flowers.

Cyclamen.—Indisputably a really well-grown cyclamen is the hallmark of a good cultivator. When buying a plant choose one which has been grown slowly in cool conditions and therefore has stiff, self-supporting stems. Failures are usually due to faulty watering. Rules cannot be formulated for correct watering, but as a generalisation the pot should be filled to the brim about once a week (*see* Health of Indoor Plants).

When annual growth dies, water can be withheld to a large extent and the corm saved for another year. It must be remembered however that while corms can be grown on for 15–20 years the *best* results are always obtained in the first season.

Mr Allan G. Langdon, an expert in growing cyclamen, wrote an excellent account of the plant in the R.H.S. *Journal* (October 1948), pp. 322–7, which may be consulted at most public libraries.

Ferns.—Some will grow in rooms, but well-grown specimens of maidenhairs and the like need first-rate cultivation. Species of *Asplenium blechnum*, and *Nephrolepis* are worth trying. Compost is made up with equal parts of fibrous loam, peat, leafsoil and coarse sand.

Ficus.—Species like *F. elastica decora* with broad, leathery, shiny leaves are often seen as window decoration in large stores. Not easy to grow in some circumstances; leaf-drop and yellowing may be caused by fluctuations in temperature or draughts, and rain-water should be used when watering.

Gloxinia.—Although often used to good effect for house decoration, the best specimens are to be found in the moist atmosphere of warm greenhouses. When grown indoors keep the plants moist in a warm room but shaded from direct sun. To encourage a succession of flowers feed fortnightly with liquid manure.

Strange as it may seem, all of the lovely forms in a wide range of colours have been selected from a single Brazilian species.

Helxine soleirolii (Mind-your-own-business).—Appropriately named from its habit of thriving where it is not wanted. Makes a pleasant mass of thin, green trailing stems. Should be kept always on the wet side.

Indiarubber Plant.—*See* Ficus.

Ivy.—Ivies show an interesting range of colour shape and size in their foliage and are to be found in many continental houses. Invaluable as climbing plants in warm rooms, the Canary Island ivy is worth trying. A related plant, raised in France, is *Fatshedera lizei*. All of these prefer a damp, leafy soil and the foliage should be sprayed occasionally.

Monstera deliciosa.—A striking plant with large deeply-cut leaves and long, thick aerial roots, many of which do not reach the ground. Often seen as a prominent decorative feature of continental homes. Requires a leafy soil and generous watering. Spray or sponge foliage regularly and avoid fluctuation of temperature in its cultivation.

Nepetahederaceavariegata(GroundIvy).—Creeping, hardy perennial native of Britain; variegated form makes an attractive addition to a hanging basket, having long stems and small kidney-shaped leaves. Correctly known botanically as *Glechoma*, not *Nepeta*. Good plant for beginners.

Palms.—Like the aspidistra, the palm is considered a relic of Victorianism, and on such slender evidence is condemned on many counts. Notwithstanding, palms of various sizes make good decorative plants. Care must be taken when re-potting, and for a number of years it is only necessary to top-dress provided that feeding is done in summer. To keep the foliage green, the leaves should be sponged regularly or, better still, the plant taken out of doors and vigorously sprayed with water from a hose.

Pelargonium (Geranium).—Ease of cultivation and beauty are found in this plant and its infinite varieties. Some of these, like "Mrs Cox," have multi-coloured leaves and are well worth hunting for in trade lists. During the summer feed generously and keep the stock vigorous by rooting cuttings annually in July–August.

Philodendron.—Mostly climbing plants with aerial roots and represented by a number of species from tropical America. Fairly tolerant of adverse conditions, but dislikes draughts and requires light shade, free watering and a rich open soil. *P. scandens*, with heart-shaped leaves, is typical of the climbing group; *P. bipinnatifidum*, with broad incised leaves, of the non-climbers.

Primula.—At Christmas time numerous varieties of primulas are offered for sale and make good presents, for with care they have a long season of flowering. Further, all are of easy culture and, if top dressed and fed, can be grown on for a year or two.

The three species grown have their origin in China and varieties of one, *Primula obconica*, may cause a rash on those susceptible to it.

Saintpaulia (African violet).—A charming dwarf with hairy leaves and pretty single and double flowers in many colours. It is a difficult plant to grow well, as it thrives in a steady temperature of 65–70°F. and a wet atmosphere. Water from below. Rotting of leaves is due to excess of moisture, draughts, cold, or gas fumes.

Sansevieria trifasciata.—Perhaps unkindly but appropriately known as Mother-in-law's tongue. It has a distinctive appearance, with stiff, erect leaves striped with gold. Keep warm and fairly dry; do not over-pot; tough.

Saxifraga sarmentosa.—Of easy culture and hardy out of doors; should be afforded a cool position and kept moist. Reddish leaves and pink flowers make it most attractive.

Setcreasea purpurea.—Visitors returning from holiday in the Canary Isles or parts of the Mediterranean often slip a cutting of this plant in their luggage. The leaves are about 4 inches long and, like the fleshy stems, are coloured a striking shade of violet-purple. Over a long period there is a succession of purple-pink flowers if afforded a warm temperature. Pieces of stems root quickly, during the summer, in sandy soil.

Although now widely grown, it is interesting to note that this plant was found growing unnoticed in a window box at Tampico Airport, Mexico, less than 25 years ago.

Solanum capsicastrum.—Commonly known as Winter, Christmas or Jerusalem cherry, this plant is a native of Madeira and is grown for its brilliant scarlet berries. If grown in a cool temperature, watered freely, and fed with liquid manure occasionally it has a long season. But it is intolerant of gas fumes which quickly cause the leaves and berries to drop. The winter cherry can be grown from year to year, but it is best to replenish the stock annually.

Tolmiea menziesii.—Although of no distinctive beauty, the pick-a-back plant is often grown indoors as it is tolerant of the worst of conditions. Young plants develop on the hairy, oval leaves, hence its common name.

Probably it was introduced from British Columbia by the Scottish plant collector, Dr Archibald Menzies. The leaves of tolmiea root easily in water.

Tradescantia (Wandering Jew).—Tolerant of neglect and makes a fine trailing plant. For best results keep moist and feed during the summer. When green shoots appear on variegated forms these should be cut out at once.

Vines.—Two of these are particularly valuable as climbing plants; *Cissus antarctica*, kangaroo vine, is a native of Australia and *Rhoicissus rhomboidea*, a Natalese plant which does not appear to have been grown to any great extent in Britain until after the Second World War.

Zebrina pendula.—Related closely to tradescantia, and often their nomenclature is confused. Like its relative, zebrina is a difficult plant to kill. Its leaves have a pleasing metallic lustre, and beneath is a shade of blood-purple. Introduced from Mexico sometime before 1850.
